

# Microscopy:

Magnification: factor by which an image appears to be enlarged

[Resolution of naked eye =  $200 \mu\text{m}$ ]

Resolving Power:  $\frac{\text{smallest distance b/w 2 objects that appear as separate objects}}{(\text{R.P.})}$

- $d \downarrow \Rightarrow \uparrow \text{ R.P.}$

$$d = \frac{0.61 \lambda}{\text{NA}}$$

NA = numerical aperture

$$\text{R.P.} \propto \frac{1}{d}$$

- RP of naked eye =  $0.2 \text{ mm}$  [ $200 \mu\text{m}$ ]
- RP of light microscope =  $0.2 \mu\text{m}$
- RP of electron microscope =  $0.2 - 0.5 \text{ nm}$

→ Magnification of compound microscope = magnification of objective lens  $\times$  magnification of eye piece/ocular lens

→ Numerical aperture (NA) =  $n \sin \theta$

( $n$  = refractive index of medium)

( $\theta$  = semi-vertical angle of cone formed by object at objective lens.)

→ electron microscope was introduced by Knoll & Ruska.

# Staining:

- Simple
- differential
- negative
- Impregnation
- special

Simple Stain: use of a single dye [Basic fuchsin or Crystal violet or Methylene blue ...]

Differential Stain: use of more than one dye (for distinguishing organisms based on their interaction with the dyes)

Gram Stain: Hans Christian Gram

### Steps:

- Prepare smear → fix with heat or methanol
- Primary stain - Crystal violet / Methyl violet / Gentian violet
- Mordant - Iodine
- Decolorisation - Alcohol / acetone / mixture of alcohol- acetone
- Counterstain - Safranine / Neutral Red / Basic Fuchsin.  
(secondary stain)

[Come In And Stain].

$\left\{ \begin{array}{l} \text{gram +ve bacteria appear bluish- purple} \\ \text{gram -ve } " " \text{ pink} \end{array} \right\}$

→ Acidic cytoplasm is what gets stained with crystal violet or safranine dye (not cell wall)

### Principles of Gram Stain:

Cell Wall Thickness: gram +ve cell wall is thicker ∴ Crystal violet is retained better

Cytoplasm: cytoplasm of gram +ve is more acidic ∴ Slower decolorization

Cell wall lipids: gram -ve cell wall has more lipids which are dissolved by

alcohol / acetone  $\Rightarrow$  pore formation  $\Rightarrow$  rapid decolorisation

$\rightarrow$  Most important step of Gram staining : Step of decolorisation

### Exceptions to Gram Stain:

- Mycoplasma (too small)
- Chlamydia }
- Rickettsia minute intracellular bacteria
- Spirochetes (very slender)
- Mycobacteria (Lipid rich cell wall  $\therefore$  stain cannot pass through)

#### Gram +ve Cocci

M *Pneumococcus*

E *Enterococcus*

S *Staphylococcus*

S *Streptococcus*

- *Helicobacter*

# Acid Fast Stains: Mycobacteria

( Acid fast bacteria appear pink )  
Non-acid fast " " blue )

→ introduced by Paul Ehrlich

→ modified by Ziehl & Neelsen (ZN)

- Heat for fixation (helps carbol fuchsin penetrate lipid layers)
- Primary Stain: Carbol Fuchsin [Basic fuchsin dissolved in phenol]
- Decolourisation: 25% Sulphuric acid
- Counterstain: Methylene blue / picric acid / malachite green

[Read: Fite stain]

Acid Fast Bacteria [Retain primary stain on decolorization]

- M. tuberculosis complex (MTBC)
- atypical mycobacterium (ATM)

} to differentiate in sputum of immunocompromised patients \*

\* MTBC → acid & alcohol fast (3% acid alcohol is decolorizer)  
ATM → only acid fast

## Kinyoun / Ziehl Stain: [cold stain]

→ similar to Ziehl & Neelsen stain (except - no heating)

→ increase conc. of phenol Carbol fuchsin  
increase time of exposure to Carbol fuchsin. }

## Partially Acid-Fast Bacteria: (Modified ZN stain)

→ they retain primary stain with a lower conc. of sulphuric acid

Acid fast with 5%  $H_2SO_4$  ⇒ *M. leprae*; oocysts of *cystoisospora*, *cyclospora* & *cryptosporidium*

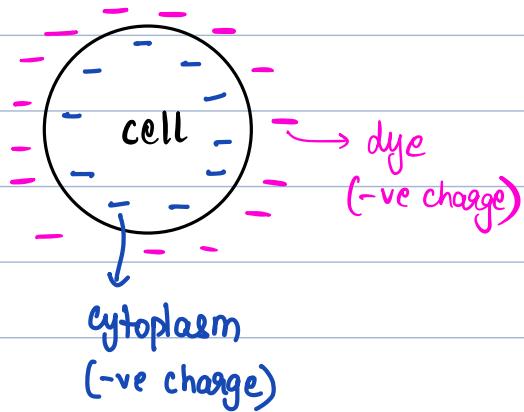

Acid fast with 0.5-1%  $H_2SO_4$  ⇒ *Legionella micdadei*  
*Nocardia*

Acid fast with 0.25-0.5%  $H_2SO_4$  ⇒ *Actinomycetes*  
*Bacterial spores*  
*Head of spear*

Stain - 5-10 mins  
Heat - 3 times with sulphuric acid until entire smear  
Wash with water until colourless  
Wash with malachite green - 1 minute

## Negative Stain:

→ use of acidic dye (India ink / nigrosine)

→ used for demonstrating capsule of bacteria & various slender bacteria (ex: Spirochetes) in fluid specimens

## Impregnation Stain: Spirochetes

→ slender bacteria are impregnated with silver to make them thick enough

### For Spirochetes

Levadite silver stain: for tissue sections

Fontana's " " : for films

## Impregnation Stain: Flagella

↳ Tannic acid

Ashby stain / Schaeffer Fulton stain → for demonstration of endospore

## Special Stains: for demonstrating special granules in bacteria

- Lipid granules: Sudan Black B
- Polysaccharide granules: Iodine stain
- Volutin (metachromatic / Babes Ernst / polar bodies) granules:
  - Albert stain
  - Neisser stain
  - Pendor stain

### Albert Stain:

Albert A stain: - Toluidine blue  $\Rightarrow$  stains volutin granules

- Malachite green  $\Rightarrow$  stains cytoplasm
- glacial acetic acid

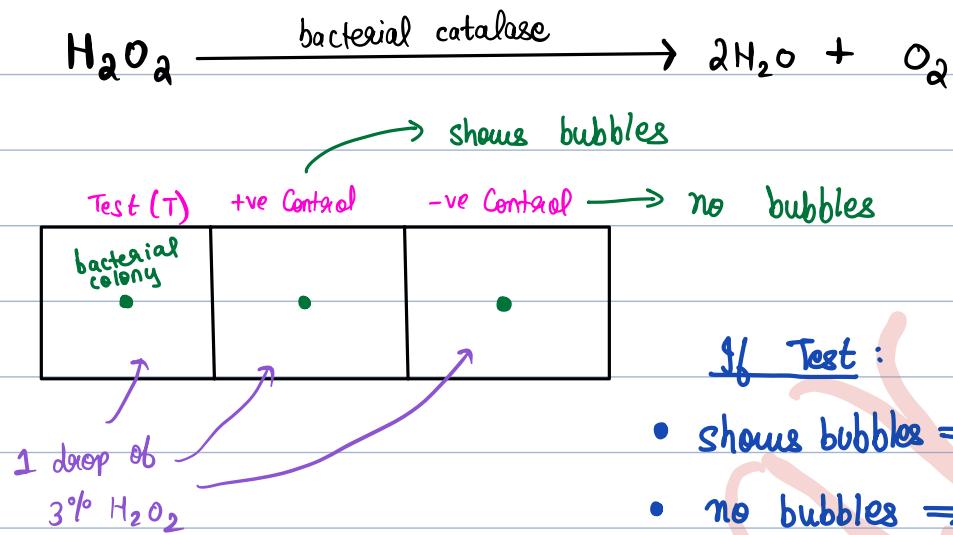

Albert B stain: - iodine

- Potassium iodide
- (mordant)

- Why are they called volutin granules? first demonstrated in Spizellum volutans
- Why " " " metachromatic granules? actually stained by toluidine blue (but they take up a bluish purple/red colour)
- What are these granules made of? Polymetaphosphate
- Do metachromatic granules take up Gram stain? Yes
  - ↓
  - (gram +ve)
- Where are they present? *Corynebacterium*, *Gardnerella vaginalis*, *Yersinia pestis*, *Bordetella pertussis*, *Mycobacterium* species.

# Biochemical Reactions: (for identification of bacteria)

## Bacterial Catalase:

(Look for gas bubbles)  
[formation of  $\text{O}_2$ ]

If Test :

- shows bubbles ⇒ Catalase Test +ve
- no bubbles ⇒ Catalase Test -ve

- Most Pathogenic bacteria are catalase positive

except:

- *Streptococcus*  
*Pneumococcus*  
*Enterococcus*
- *Anaerobes* - *Actinomyces*  
*Bacteroides*  
*Clostridium*  
*Lactobacillus*
- *Shigella dysenteriae* - type 1.

## Oxidase Test:

TMFD  $\xrightarrow{\text{bacterial cytochrome C}}$  Purple/Blue compound  
(tetra-methyl-para-phenylene  
diamine - dihydrochloride)

Dont use - straight wire  
- Nichrome inoculating loop } give  
False +ve  
oxidase  
test.

Most pathogenic bacteria are oxidase test positive  
except :

*Corynebacterium*

*Enterobacteriaceae*

*Staphylococcus*

*Streptococcaceae*

# Utilization of Sugars:

Hugh - Leifson's oxidative fermentation medium

↳ glucose + bromothymol blue  
(pH indicator)

## If bacterial colony:

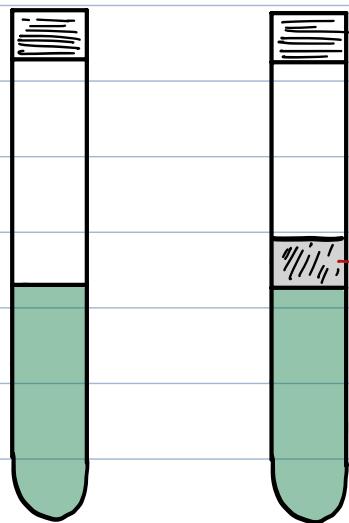

- breaks down the sugar  $\Rightarrow$  **saccharolytic**
- doesn't break down sugar  $\Rightarrow$  **asaccharolytic**

only aerobic

**OXIDATIVE**

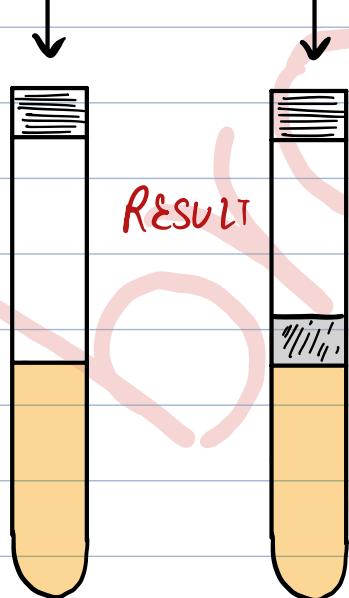

aerobic + anaerobic

**FERMENTATIVE**

oil overlay  $\Rightarrow$  to create anaerobic conditions  
(sterile petroleum jelly)

Bromothymol blue has changed colour

acid has been produced aerobically & anaerobically

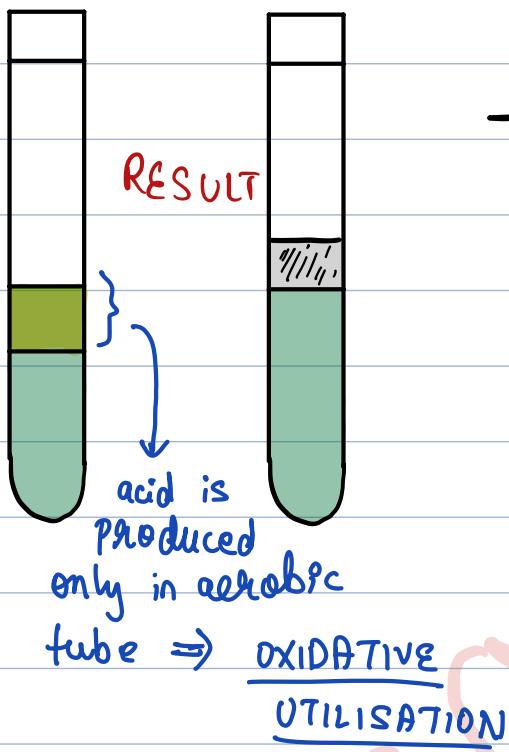

$\therefore$  bacterial colony

is FERMENTATIVE

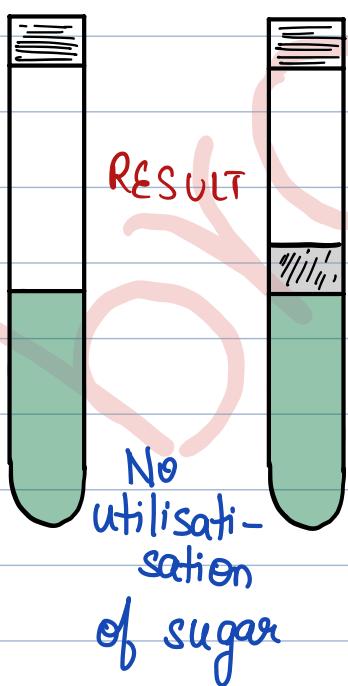

## Fermentative Utilisation [Facultative Anaerobes]:

- Enterobacteriaceae
- Staphylococci
- Streptococci
- Haemophilus

### Start Aerobes:

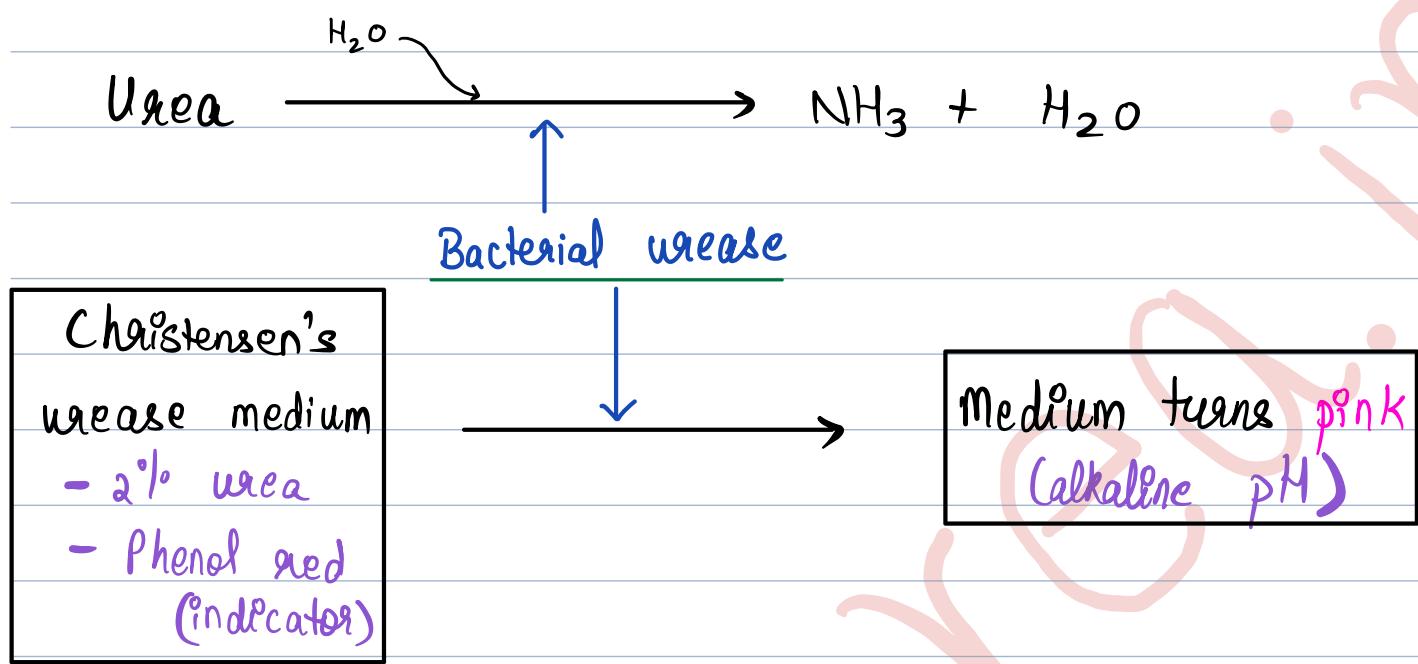

- Pseudomonas
- Brucella
- Bordetella
- Micrococcus

### ASACCHAROLYTIC:

- Moraxella
- Acinetobacter
- Compylobacter
- Helicobacter

## Urease Test :

## Urease Positive Bacteria:

**P**roteus

**U**reaplasma

**N**ocardia

**C**ryptococcus

**H**elicobacter  $\rightarrow$  maximum urease producing bacteria

**M**organella

**S**taphylococcus aureus & **S**taphylococcus epidermidis & **S**taphylococcus saprophyticus

**K**lebsiella pneumoniae

**B**rucella

Coagulase Test  
Bile solubility Test  
Optochin Sensitivity  
Bile Resistance  
Bacitracin Sensitive  
Indole Positive  
Indole Negative

Enterococcus  
Streptococcus Pyogenes  
E. Coli  
Klebsiella

Citrate utilty

Indole

Triple Sugar Iron

Black discolouration — due to  $H_2S$  & iron deposit

Mannitol Motility

## Bacterial Typing: intraspecies strain characterization

Purpose of typing - epidemiologic studies (outbreak studies)

- virulent & avirulent studies
- studies of transmissibility
- relapse vs. reinfection
  - (from same strain)
  - (from different strain)

## Typing Methods

## Phenotypic

## Genotypic

## Phenotypic - Serotyping:

→ use of surface antigens (and their reaction with antibodies)

*Streptococcus pyogenes*

graffith Typing (M protein)

> 120 M types

*Streptococcus pneumoniae*

Capsular antigen

~ 95 serotypes

*E. coli*

O antigen

> 170 'O' serotypes

## Phenotypic - Biotyping:

→ for selected group of biochemical reactions

• I to VIII types of *Haemophilus influenzae*

↳ chemicals used - Indole

- Ornithine

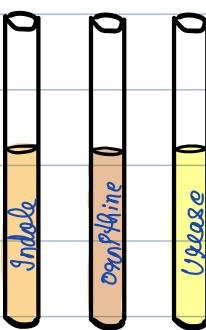

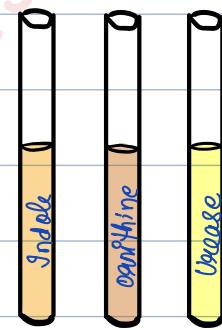

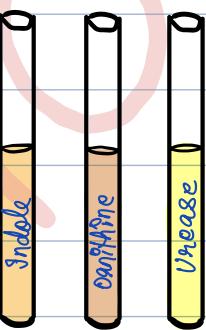

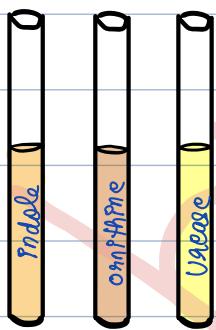

- Urease

Isolate A

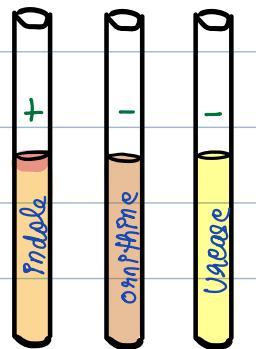

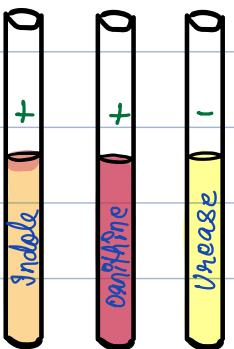

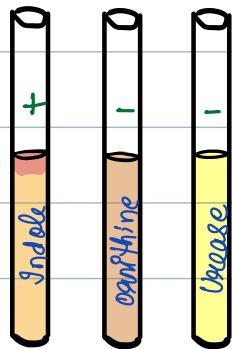

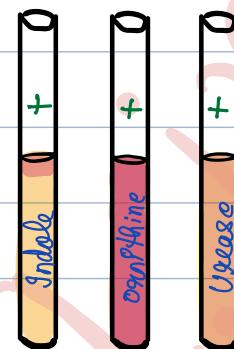

Isolate B

Isolate C

Isolate D

↓ overnight incubation

Isolate AIsolate BIsolate CIsolate D

Same strain

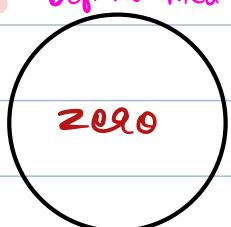

- *Corynebacterium diphtheriae* → 4 biotypes
  - gravis
  - intermedius
  - mitis
  - beijantii
- *Vibrio cholerae* O1 →
  - El Tor
  - classical

### Phenotypic - Auxotyping:

→ based on their ability to utilize / not utilize a specific group of substrates

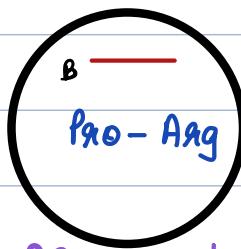

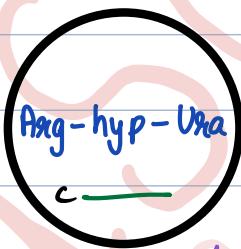

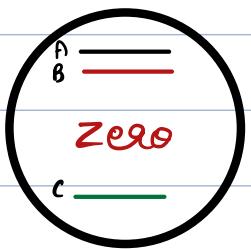

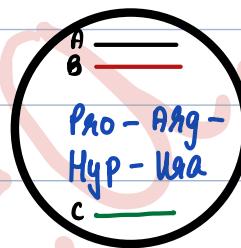

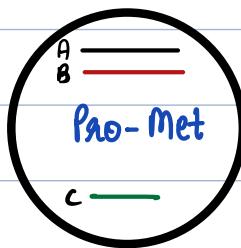

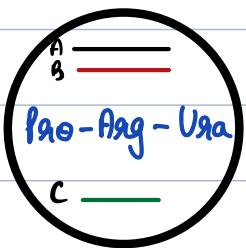

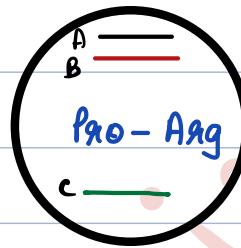

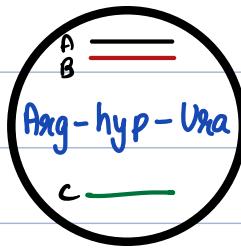

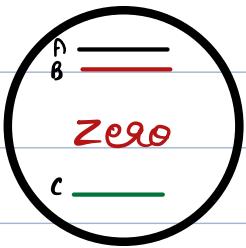

Defined medium

- *Gonococcus*:

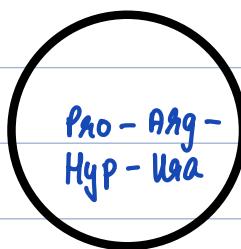

⇒ contains all essential nutrients required for growth of gonococcus

many media were created by deleting a set of ingredients

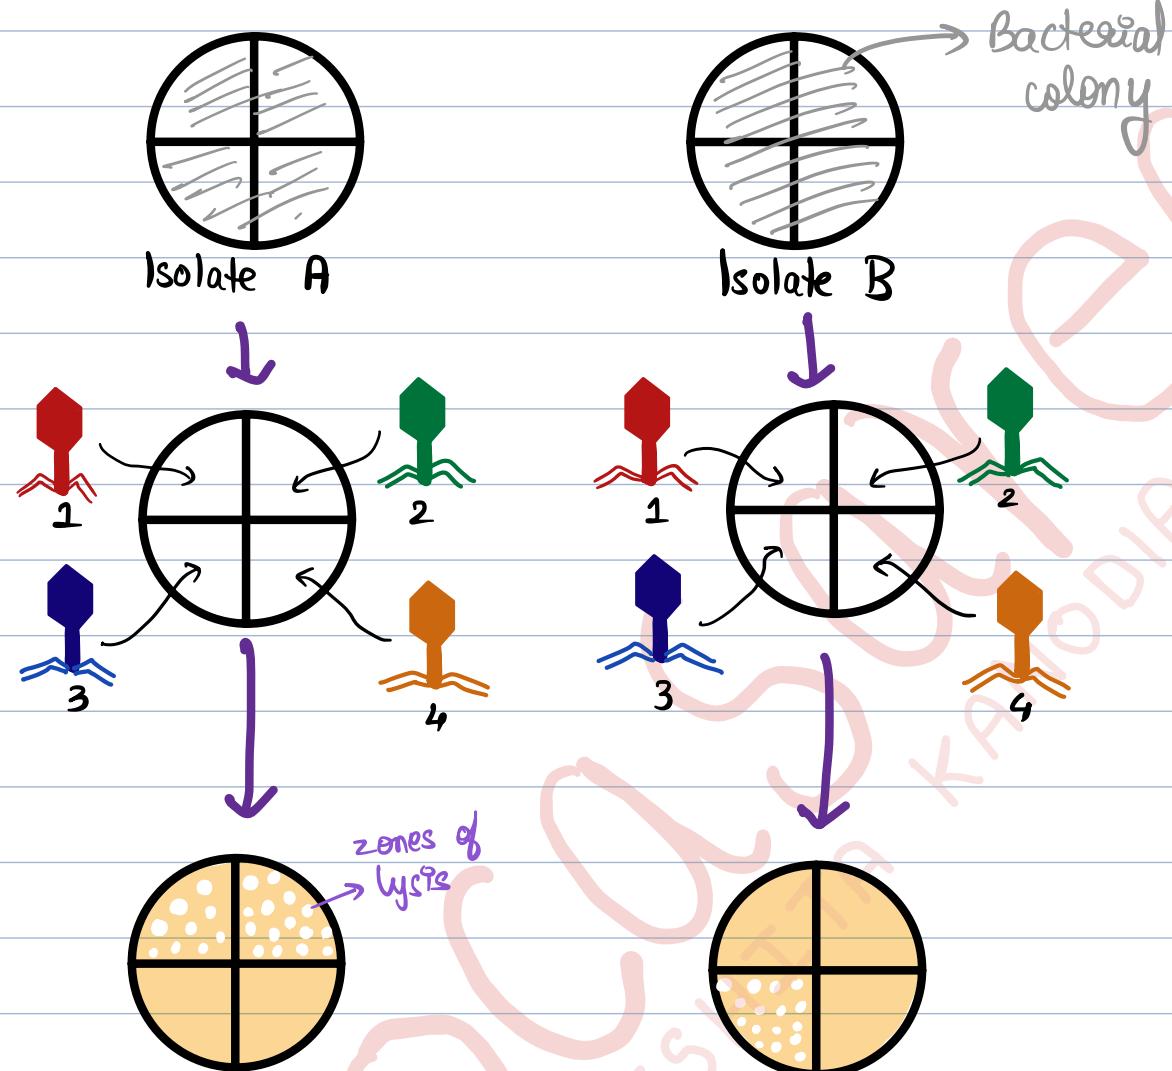

AHU- oxotype

PM- auxotype

## Phenotypic - Phage Typing :

→ on the basis of susceptibility to a standard set of bacteriophages.

Phage Type 1, 2  
(Bacterial colony is  
susceptible to phage 1 & 2)

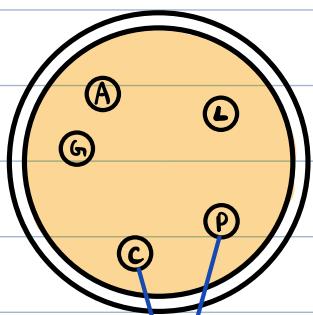

Phage type 3  
(bacterial colony is  
susceptible to phage 3)

- *Staphylococcus aureus*
- *Corynebacterium diphtheriae*
- *Salmonella*
- *Vibrio*

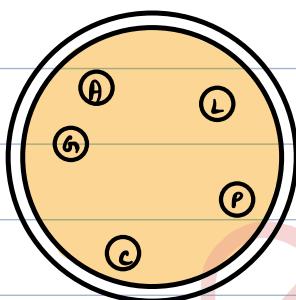

# Phenotypic - Antibiogram Typing:

→ based on susceptibility / sensitivity to antibiotics

Strain A

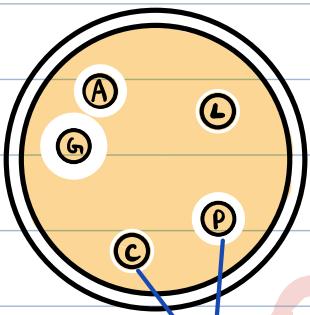

Strain B

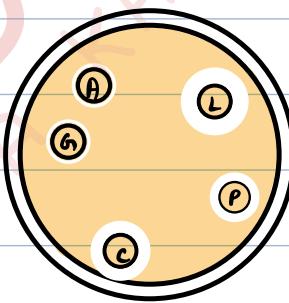

overnight  
incubation

Strain A

zone of  
inhibition (white area)

Strain B

- if small  $\Rightarrow$  more resistance to that antibiotic

- if large  $\Rightarrow$  less resistance / no resistance to that antibiotic

- *Proteus vulgaris*

Phenotypic - Bacteriocin Typing: susceptibility of standard strains to bacteriocin secreted by isolates

Phenotypic - Whole Cell Protein Typing: Relative mobilities under electrophoresis of total extracted protein

Phenotypic - Multi Locus Enzyme Electrophoresis [MLEE]: Relative mobilities under electrophoresis of specific intra-cellular enzymes

## GENOTYPIC METHODS: superior to phenotypic methods

→ DNA based analysis

→ a particular part / whole DNA is extracted out  $\Rightarrow$  restriction endonucleases  
↓

banding pattern is checked  $\Leftarrow$  gel electrophoresis  $\Leftarrow$  DNA fragments

### Plasmid profile analysis

#### Ribotyping

Pulsed field Gel Electrophoresis [PFGE]

Restriction Fragment Length Polymorphism [RFLP]

Nucleic Acid Sequencing  $\rightarrow$  GOLD STANDARD METHOD FOR

↓

TYPPING

whole genome sequencing will take  
a lot of time

↓

$\therefore$  there is —

#### Multilocus Sequence Typing [MLST]:

→ only particular standard house keeping genes are sequenced  
& compared

# Bacterial Cultivation:

Phototrophs: bacteria that can utilize light as a source of energy

Chemotrophs: bacteria that need to undergo chemical reactions to synthesize energy

Autotrophs      Heterotrophs

Autotrophs: can utilize inorganic sources (in the form of atmospheric gases) of carbon & nitrogen

Heterotrophs: require pre-formed organic compounds for undergoing [chemo-organotrophs] chemical reactions

Most Human commensals & pathogens  $\Rightarrow$  heterotrophs ( $\because$  culture media have to be provided for their growth)

$\rightarrow$  Louis Pasteur  $\Rightarrow$  established bacterial growth requirements  
 ↳ father of medical microbiology (liquid media / nutrient broth)

Advantages of Liquid Media: convenient

$\rightarrow$  bacterial multiplication is rapid

$\rightarrow$  originally clear solution becomes turbid  $\Rightarrow$  microbial growth

Disadvantages: quantitative analysis cannot be done

$\rightarrow$  bacterial strains cannot be isolated.

Robert Koch  $\Rightarrow$  introduced solid media

Advantages of Solid media: different bacterial colonies can be clearly seen

Disadvantage: slower growth than liquid media

### Solidifying Agents:

Gelatin: derived from animal bone / hide

$\rightarrow$  15% concentration

$\rightarrow$  Disadvantages: - certain bacteria can proteolyse gelatin

- liquefies above  $24^{\circ}\text{C}$  (but incubator  $\Rightarrow 37$  or  $38^{\circ}\text{C}$ )

(polysaccharide)

Agar-Agar / Chincere gelase: sea weeds & red algae

$\rightarrow$  2% concentration

$\rightarrow$  inert substance  $\therefore$  does not provide nutrition to bacteria ; it neither promotes nor inhibits bacterial growth

$\rightarrow$  Liquefies  $> 98^{\circ}\text{C}$

Solidifies  $< 42^{\circ}\text{C}$   $[42-98^{\circ}\text{C} \Rightarrow$  semisolid]

$\rightarrow$  soft agar: used to check motility of bacteria

- Conc. = 0.2 - 0.5%

$\rightarrow$  firm agar: used for inhibition of swarming.

- conc. = 5-6%

### Swarming bacteria:

- *Clostridium tetani*
- *Bacillus cereus*

} gram +ve

- *Vibrio alginolyticus*
- *Proteus vulgaris*
- *Proteus mirabilis*

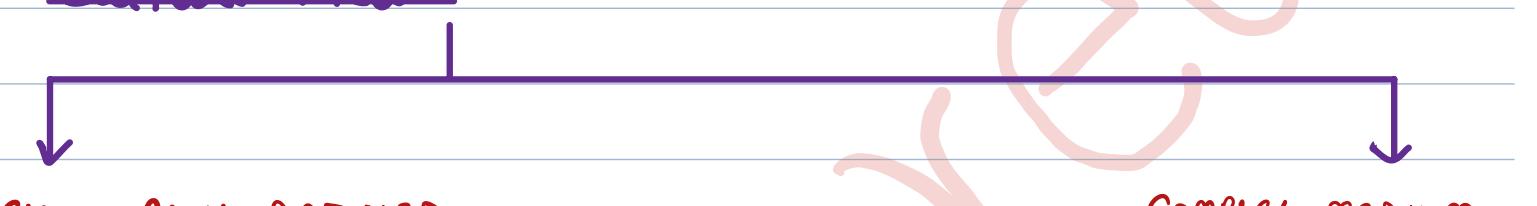

} gram -ve

## Constituents of Culture Media:

- Peptones
- Meat / yeast extract
- Casein hydrolysate
- Electrolytes
- Water

Sources of C & N.

## Culture Media:

### CHEMICALLY DEFINED

→ exact composition is known

### COMPLEX MEDIUM

→ exact composition not known

Simple / Basal / Basic Medium: only non-fastidious bacteria can grow

→ source of C & N only

require only C & N for their survival.

Eg: - peptone water

- nutrient broth (peptone water + meat extract)

- nutrient agar (nutrient broth + agar)

Enriched Medium: for fastidious bacteria

→ egg / blood / serum is added

Eg: - blood agar (autoclaved nutrient agar + 5% sterile sheep blood)  
cooled to 50°C

- chocolate agar (autoclaved nutrient agar + 5% sterile sheep blood)  
(RBC's get lysed at 75°C)  
cooled to 75°C

- Loeffler's serum [Corynebacterium diphtheriae]
- Lowenstein Jeneen medium [Mycobacterium tuberculosis]

## Selective Medium: (solid medium)

→ a component is added which inhibits the growth of unwanted bacteria  
(only allows growth of specific bacteria)

e.g. - MacConkey (mildly selective for gram -ve bacteria)  
→ contains <sup>\*</sup> Na taurocholate, bile salt

\* Exception: Staphylococcus } gram → can grow on MacConkey  
Enterococcus } +ve

- EMB [Eosine Methylene Blue Agar] (mildly selective for gram -ve bacteria)

- Salt Agar [selective for Staphylococci]

(all staphylococci have the special property of being able to grow in 7-10% salt)

- Crystal Violet Blood Agar [selective for Streptococcus pyogenes]

- Thayer Martin [selective for Neisseria]

→ contains antibiotics

- TCBS [thiosulphate citrate bile salt sucrose agar]

(selective for vibrio)

- Cetrimide agar (selective for pseudomonas)

- Potassium tellurite (selective for Corynebacterium)

- PLET (Polymyxine lysozyme EDTA thallus acetate)  
(Bacillus anthracis)

- MYP A (mannitol egg-yolk phenyl red polymyxine agar)  
(Bacillus cereus)

## Enrichment Medium:

→ liquid selective medium

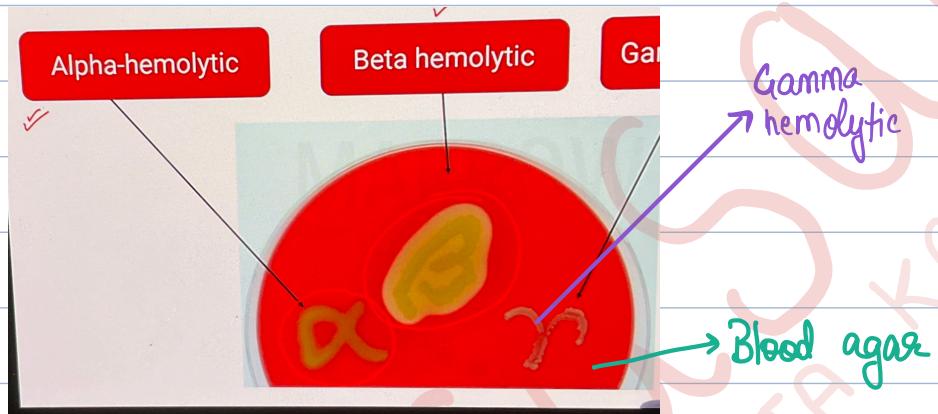

Ex: - APW (alkaline peptone water)  $\Rightarrow$  Vibrio

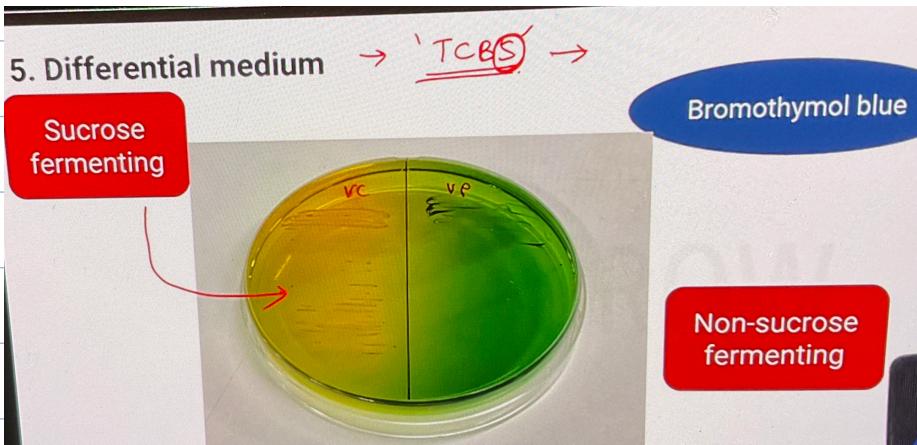

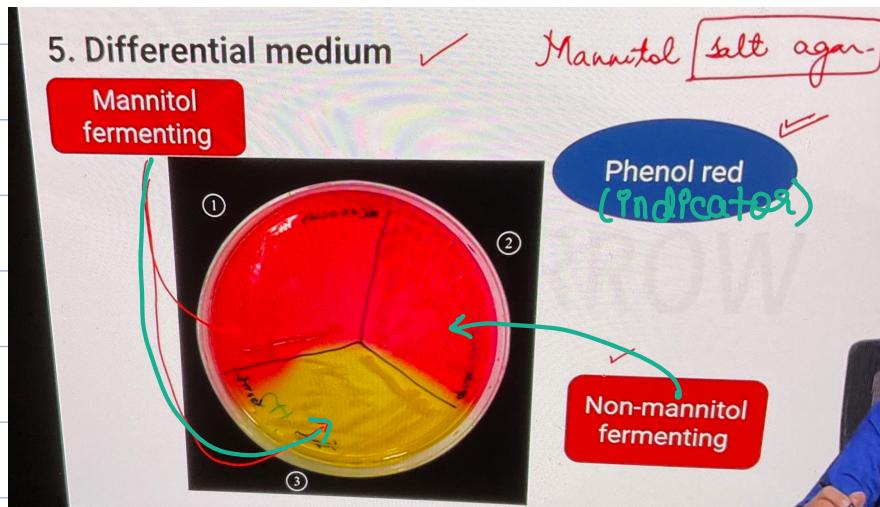

- Selenite F  $\Rightarrow$  Salmonella & Shigella

- Tetrathionate broth  $\Rightarrow$  Salmonella  
faeces

## Differential Medium:

→ colony morphology/colour differentiates the bacteria.

## Indicator Medium:

→ special component is added which indicates the growth of a particular group of bacteria.

Eg:

- MacConkey → Neutral red
- TCBS → Bromothymol blue
- MSA → Phenol red

## Transport Medium:

→ medium which just maintains the original count of bacteria in a clinical specimen

Eg:

- Venkatraman Ramakrishnan Medium ⇒ Vibrio
- Pike's ⇒ Streptococcus pyogenes
- Stuart's }
- Amie's } ⇒ *Neisseria*
- Thioglycolate ⇒ anaerobes
- Cary Blair ⇒ UNIVERSAL STOOL TRANSPORT MEDIUM

# Culture Techniques:

## Streak Culture:

- Primary well
- sterilize the inoculating loop by heating ↗  
then slightly cool it.
- create primary streaks
- sterilize the loop again
- turn the plate & make secondary streaks
- sterilize the loop
- turn the plate & make tertiary streaks
- finally, make the tail

## Lawn Culture:

take a sterile cotton swab & dip it  
into the inoculum

swab it completely

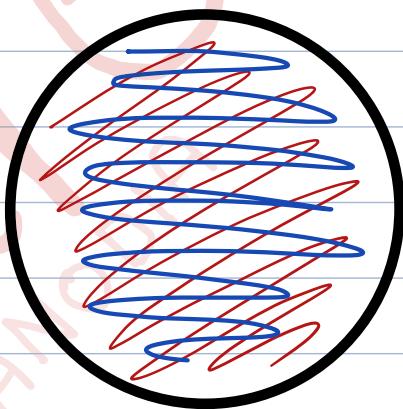

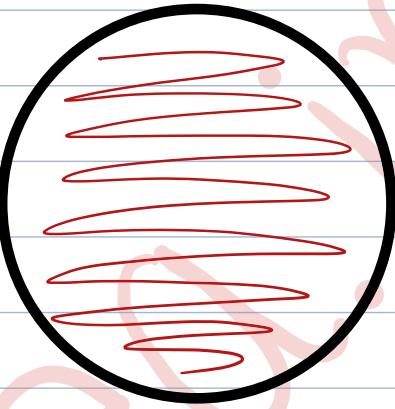

make a circle at the periphery

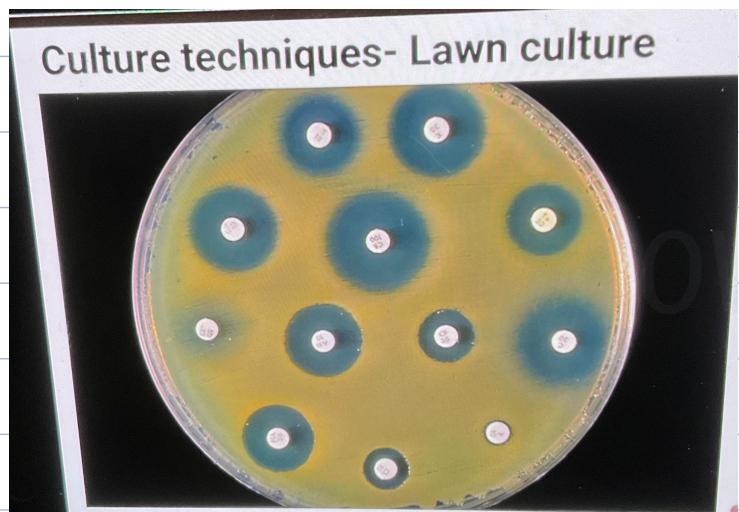

turn the plate to different angles

swab completely everytime  
(& make a circle)

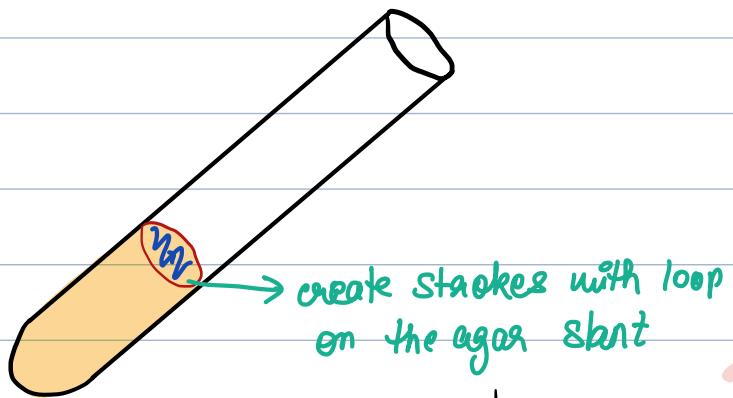

- **Lawn culture** is typically used for antibiotic - sensitivity testing.

## Stroke Culture:

→ generally used for biochemical tests

create strokes with loop  
on the agar slant

↓

flame the test tube

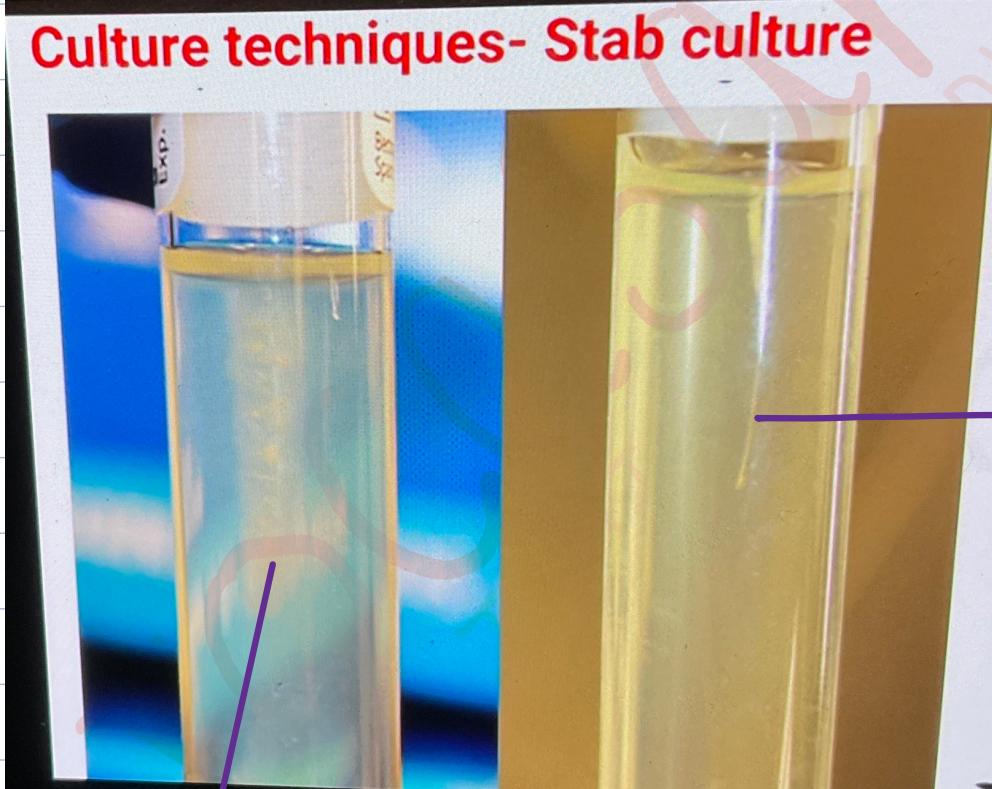

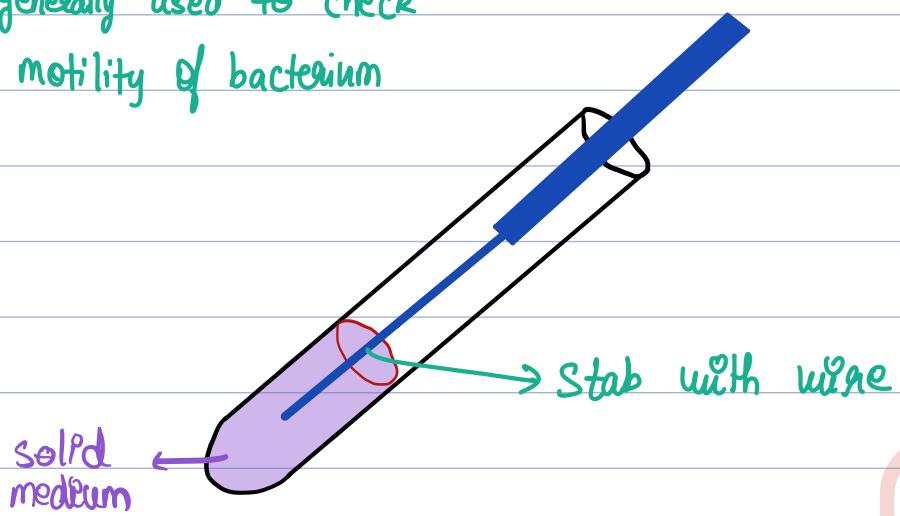

↓

plug it with cotton

Stab Culture: use straight wire (not loop)

↳ generally used to check  
motility of bacterium

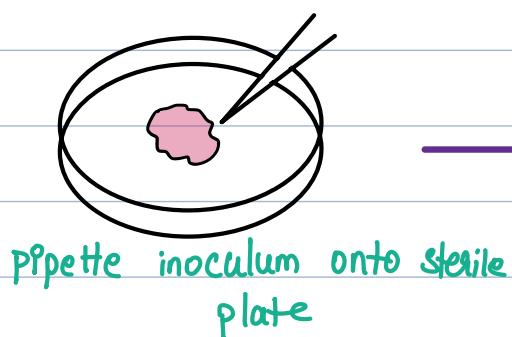

motile  
bacteria

non-motile  
bacteria

## Pour Plate Culture:

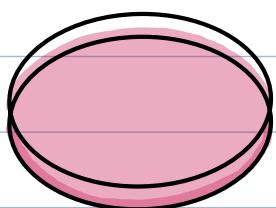

→ used for quantification of bacteria in specimen.

Pipette inoculum onto sterile plate

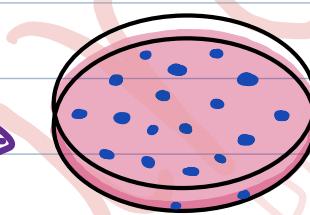

add sterile medium

swirl to mix & incubate

Colonies grow in & one the medium

# Antibiotic Susceptibility Tests (AST):

- Purpose — guideline for right antibiotic
  - to study susceptibility patterns in a hospital / community

[AB = antibiotic]

## Minimum Inhibitory Concentration: (MIC)

- lowest concentration of AB that just inhibits the growth of bacteria in the medium.

## Minimum Bactericidal Concentration: (MBC)

- lowest concentration of AB, that kills all bacteria in the medium

$$MBC > MIC.$$

## Methods of AST:

- To control the impact of environmental factors, the conditions for susceptibility testing are extensively standardised:
  - Dilution (Micro broth dilution method)
  - DPSc diffusion
  - E-test
  - Automated
    - MICROSCAN WALKAWAY
    - PHOENIX
    - VITEK - 2

(a) Antimicrobial content

(b) Standard inoculum of Test Isolate

(c) Reliable medium [Mueller Hinton Agar/Broth] \*

(d) Standard temperature of incubation [35-37°C]

(e) Standard duration of incubation [16-18 hrs]

(f) Quality control strains

\* Mueller - Hinton Medium  $\Rightarrow$  casein hydrolysate agar / broth

→ Some bacteria cannot grow on Mueller-Hinton medium

→ For those bacteria, extra supplements have to be added

Eg: - *Pneumococcus*  $\Rightarrow$  lysed horse blood / sheep blood added

- *Staphylococcus aureus*  $\Rightarrow$  2-4% salt added

### Standard Inoculum Preparation:

$\Rightarrow$  0.5 McF turbidity ( $McF = Mac\ Farland's$ )  
 $\rightarrow 1.5 \times 10^8 CFU / mL$ .

Eg: *E. coli* (urine)

[ $CFU =$  colony-forming units]

$\rightarrow$  Sterile peptone water + few *E. coli* colonies

$\rightarrow$  Incubate for few hours

$\rightarrow$  measure turbidity using - spectrophotometer or  
 $- McFarland's$  standard media

{  $MHA =$  Mueller Hinton Agar }  
 $MHB =$  Mueller Hinton Broth }

### [AST-1] Dilution Method: [Reference Method]

Prepare serial dilution of antibiotics on MHA / MHB.

+

fixed amount of standard inoculum

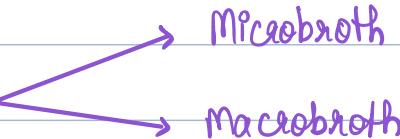

Incubate at 35-37°C for 16-18 hours (overnight)

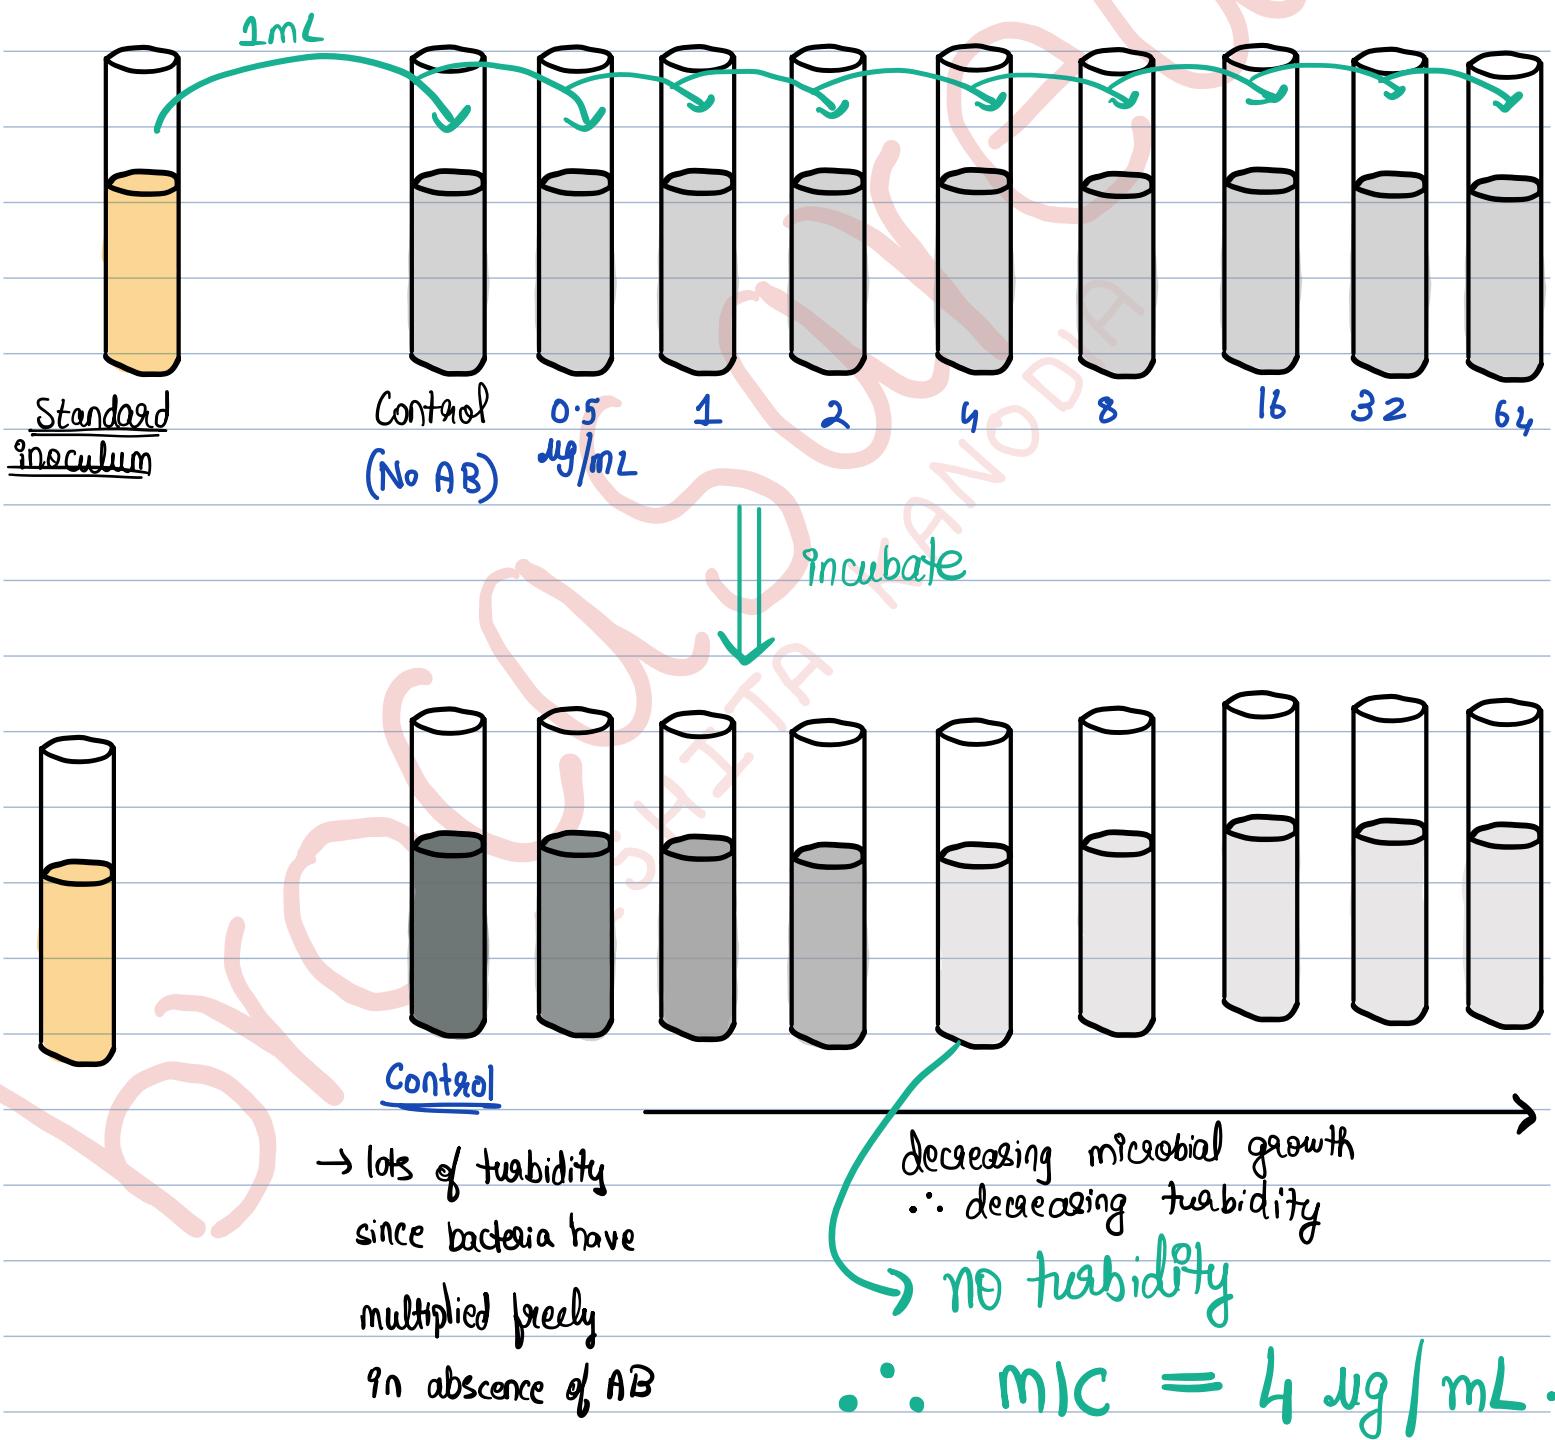

Determine the MIC.

## Types of Dilution Methods :

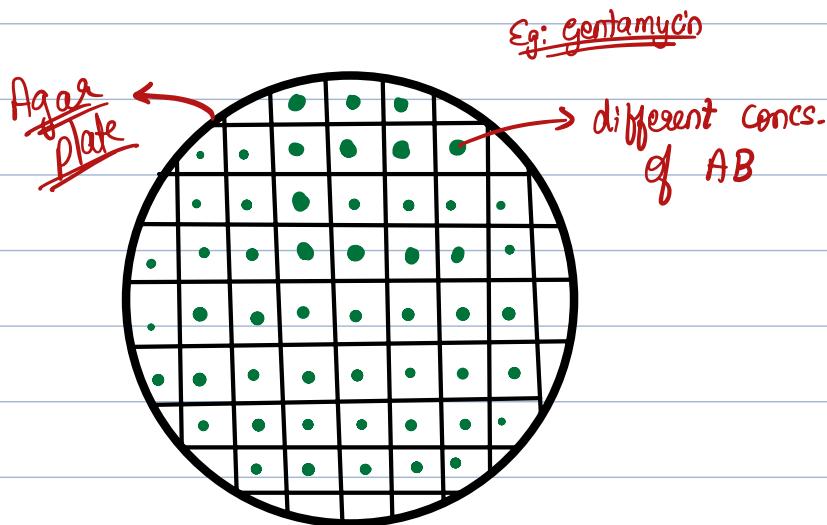

Broth Dilution : 

## Agar Dilution

### Macro-broth dilution Method :

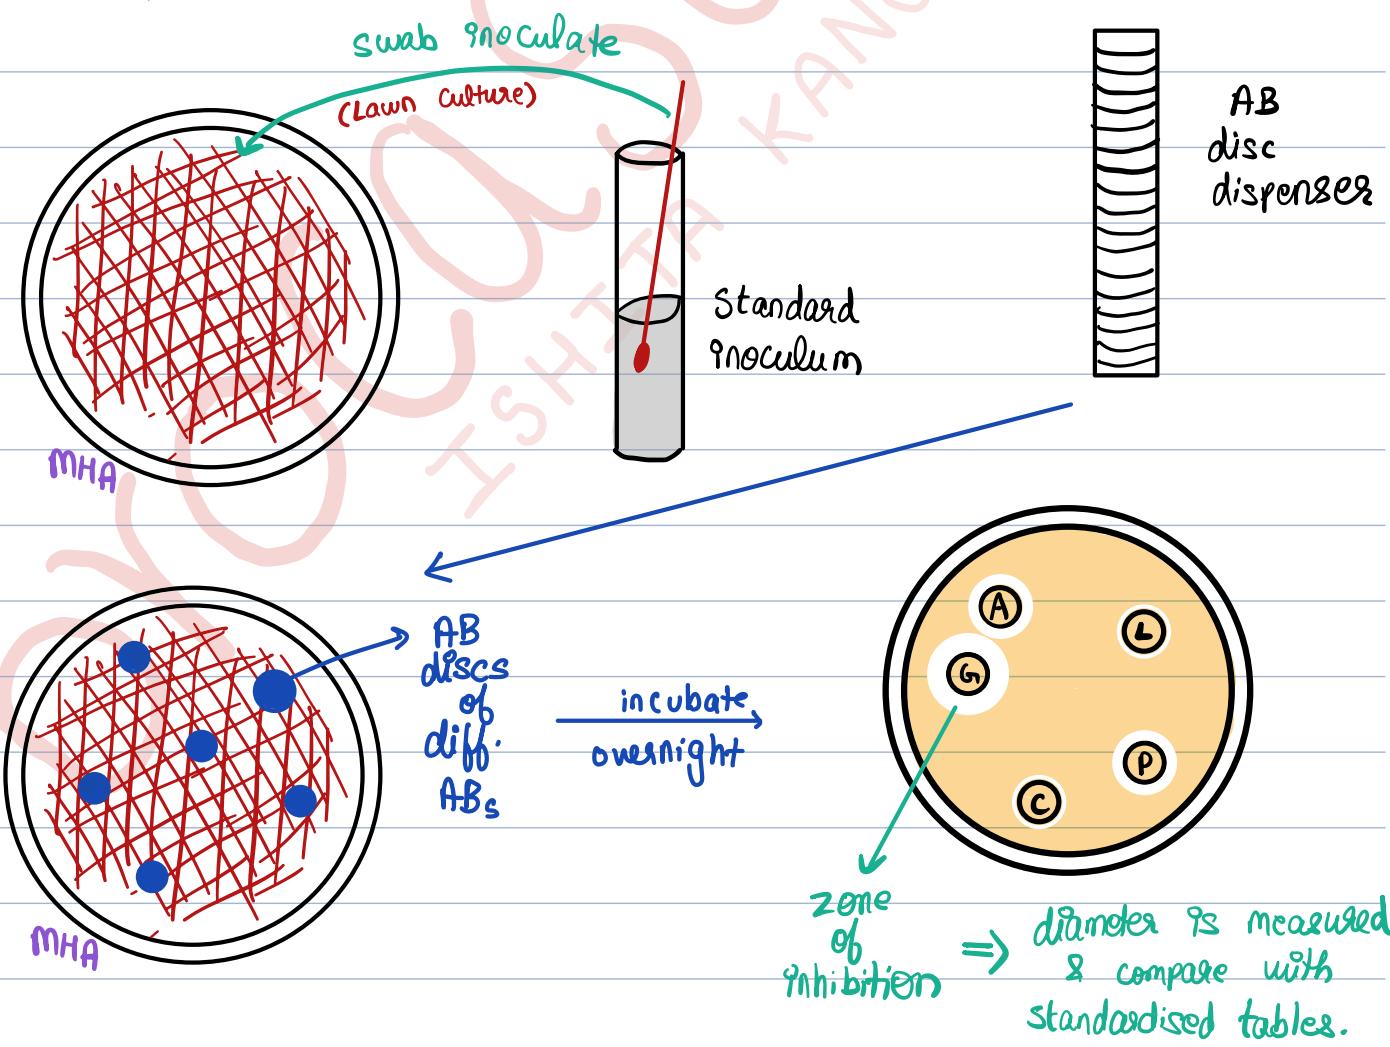

## Agar Dilution Method :

## [AST-2] Disc Diffusion Method: Kirby Bauer Method

- AB discs impregnated with a standardised conc. of AB
- uses MMA

## Sensitive

→ organism is inhibited by the recommended dose of antimicrobial agent at the infection site.

## Intermediate

→ organism may require a higher dose of AB for a longer period of time to be inhibited

## Resistant

→ Organism is not inhibited by the recommended dose of the antimicrobial agent at the site of infection

### Advantages of Kirby Bauer Disc Diffusion:

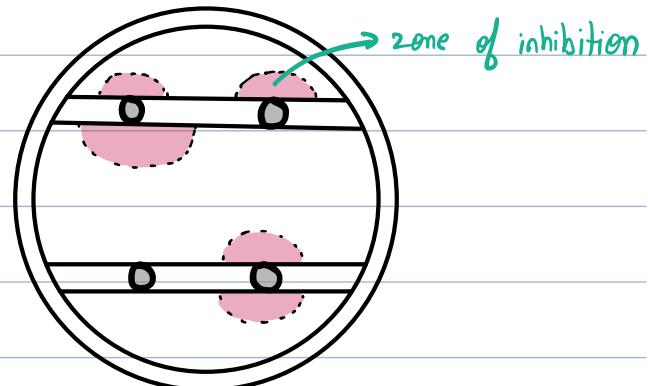

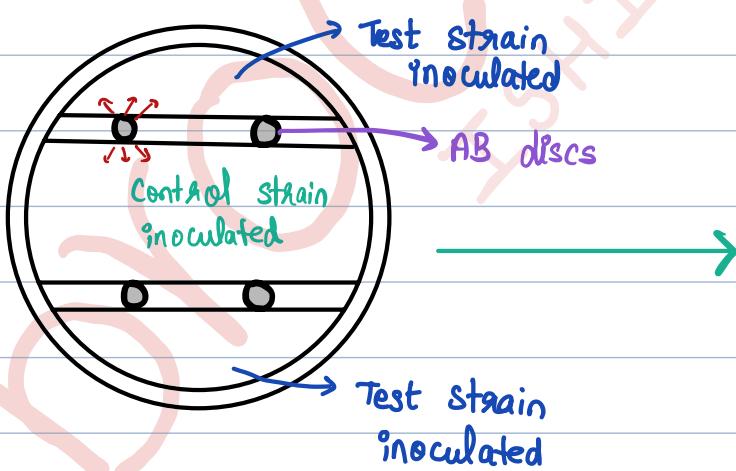

- easy to do
- easy to interpret

### Disadvantages of Kirby Bauer Disc Diffusion:

- does not quantify the MIC (qualitative only)

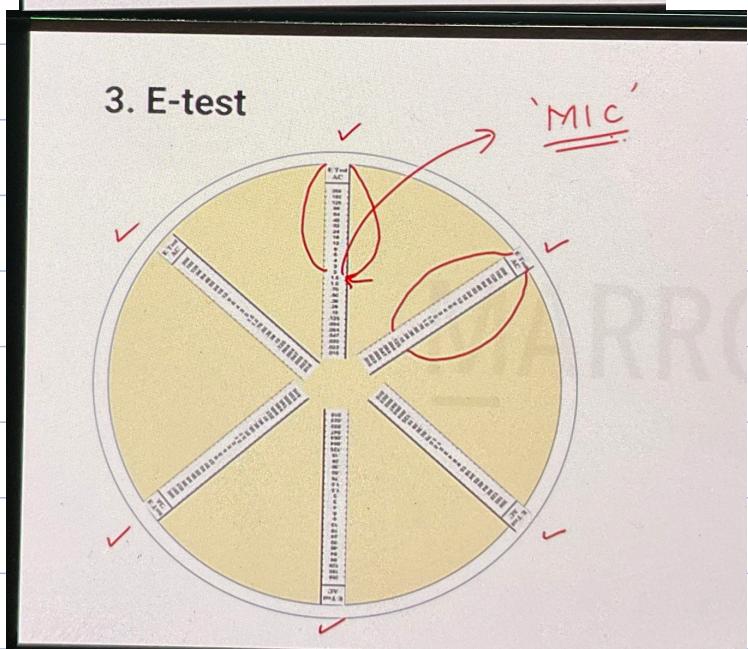

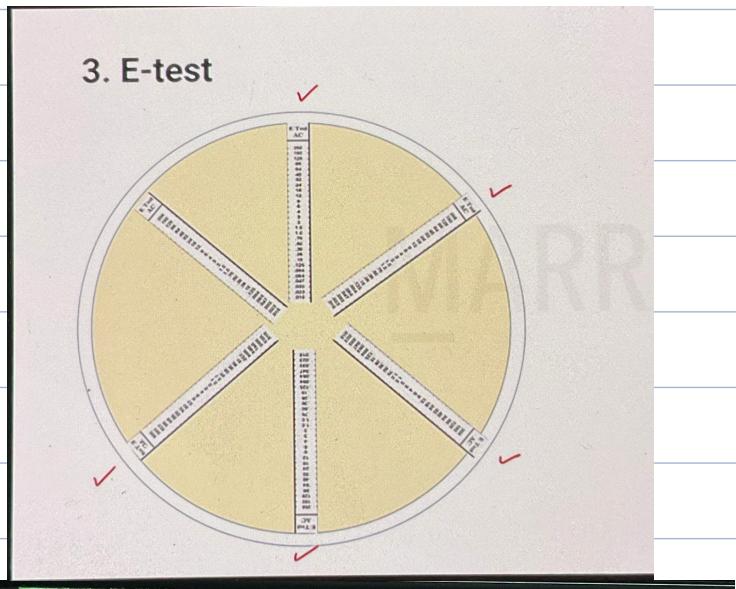

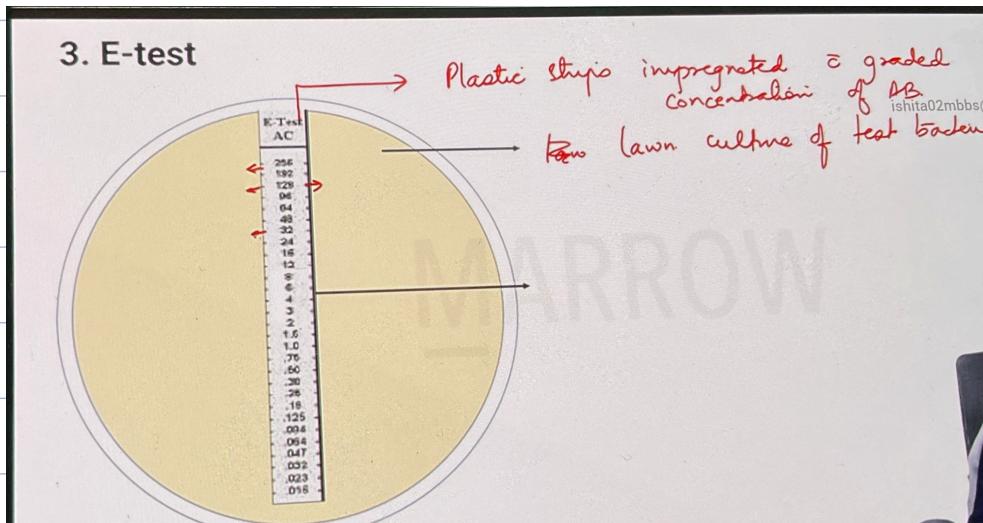

### Stoke's Disc Diffusion Method:

- test & control strains are inoculated on the same petri plate.

## [AST-3] Epsilometer Test [E-Test]:

→ combination of dilution method & disc diffusion method

## [AST-4] Automated Methods:

- MICROBROTH WALKAWAY
- PHOENIX
- VITEK - 2.

# Antimicrobial Resistance Mechanisms:

Beta-lactams: inhibit cell wall synthesis by binding to transpeptidases - penicillin binding proteins [PBP's]

Glycopeptides: bind to cell wall precursors [D-ala-D-ala]  
∴ inhibit cell wall synthesis

Aminoglycosides } bind to 30s ribosome subunit  
Tetracyclines } ∴ inhibit protein synthesis

Macrolides } bind to 50s ribosome subunit  
Chloramphenicol } ∴ inhibit protein synthesis

Fluoroquinolones: inhibit DNA replication by binding to DNA gyrase / topoisomerase IV

Sulfonamide } inhibit folate synthesis  
Trimethoprim }

Inherent Resistance : innate ability of bacterium to resist killing by AB by its inherent structural / functional characteristics

- (a) reduced entry (bacteria is impermeable to AB)
- (b) extrusion of AB by inherently encoded transporters
- (c) inherent production of enzymes that inactivate the AB

Eg:

- Enterococci & Anaerobes — aminoglycosides — reduced entry
- Gram +ve bacteria — Aztreonam — lack of PBPs to which Aztreonam binds
- Gram -ve " — Vancomycin — no entry

Acquired Resistance:

→ May be due to — Mutations

— Horizontal transfer

Eg:

- Streptococcus pneumoniae — by transformation
- Staphylococcus aureus — by transduction

Most common mode of horizontal transfer in bacteria — Conjugation.

## Modes of Antibiotic Resistance:

Inactivating enzymes: most common mode

Eg: A → aminoglycosides - inactivated by phosphorylation, N-acetylation  
 B →  $\beta$  lactams - hydrolysis of amide bond in  $\beta$  lactam ring by  $\beta$  lactamases  
 C → chloramphenicol - acetyl transferases inhibit.

## Decreased Permeability:

→ absence of porins or outer membrane proteins [OMPs] which prevents entry of AB

Eg: - Resistance to  $\beta$ -lactams in gram -ve  
 - aminoglycosides  
 - Macrolides  
 - Fluoroquinolones

## Antibiotic Efflux: most common mode of resistance to Tetracyclines.

Eg: - Macrolides  
 - Fluoroquinolones  
 -  $\beta$ -lactams

## Altered Drug Target Sites: • ribosome alterations

Eg: - Aminoglycosides  
 - Macrolides

• Cell wall precursors

Eg: - Resistance to Vancomycin

- altered enzymes

Eg: - Methicillin resistant staphylococcus aureus  
- fluoroquinolones (MRSA)

Protection of Target Sites: bacteria synthesize ribosomal protection proteins (RPP).

Eg: - Tetracycline resistance

Overproduction of Drug Targets:

Eg: -  $\beta$ -lactam resistance in gram +ve  
- sulphonamide resistance

Bypass of Antibiotic Inhibition:

Eg: - Sulphonamide resistance

MRSA

# Bacteriophages: viruses that infect bacteria

## Cycles of Phage:

### Lytic Cycle:

bacteriophage binds to bacterium

infects it DNA into cytoplasm

stops bacterial metabolism

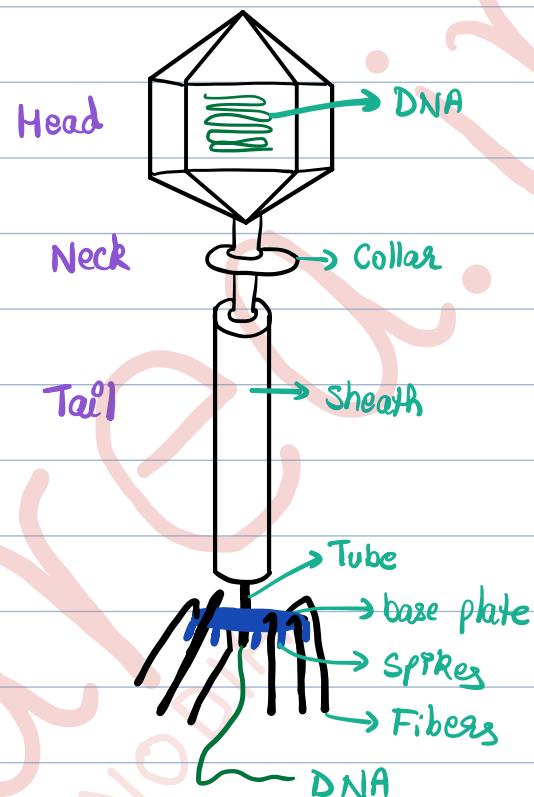

Fragmentation of bacterial chromosome

Synthesis of phage components using bacterial enzymes

Assembly of daughter phage

Induced lysis of bacterium causes the daughter phage to move out of the bacterium

Infection of new bacterium

## Lysogenic Cycle:

bacteriophage binds to bacterium

↓  
injects its DNA into cytoplasm

↓  
phage DNA gets integrated with bacterial chromosome to form **prophage**

↓  
As bacterium undergoes binary fission, prophage is passed on to future generations of bacteria

↓  
If any of these bacteria are exposed to chemicals/radiations

↓  
Phage DNA disintegrates from bacterial chromosome

↓  
phage DNA enters lytic cycle

## Types of Phages:

- phages that can follow only lytic cycle  $\Rightarrow$  **VIRULENT PHAGES**  
Eg: -  $T_1$ ,  $T_2$  phages of  $E. coli$ .
- phages that enter lysogenic & then lytic cycle  $\Rightarrow$  **TEMPERATE PHAGES**  
Eg: -  $\lambda$  phage of  $E. coli$ .

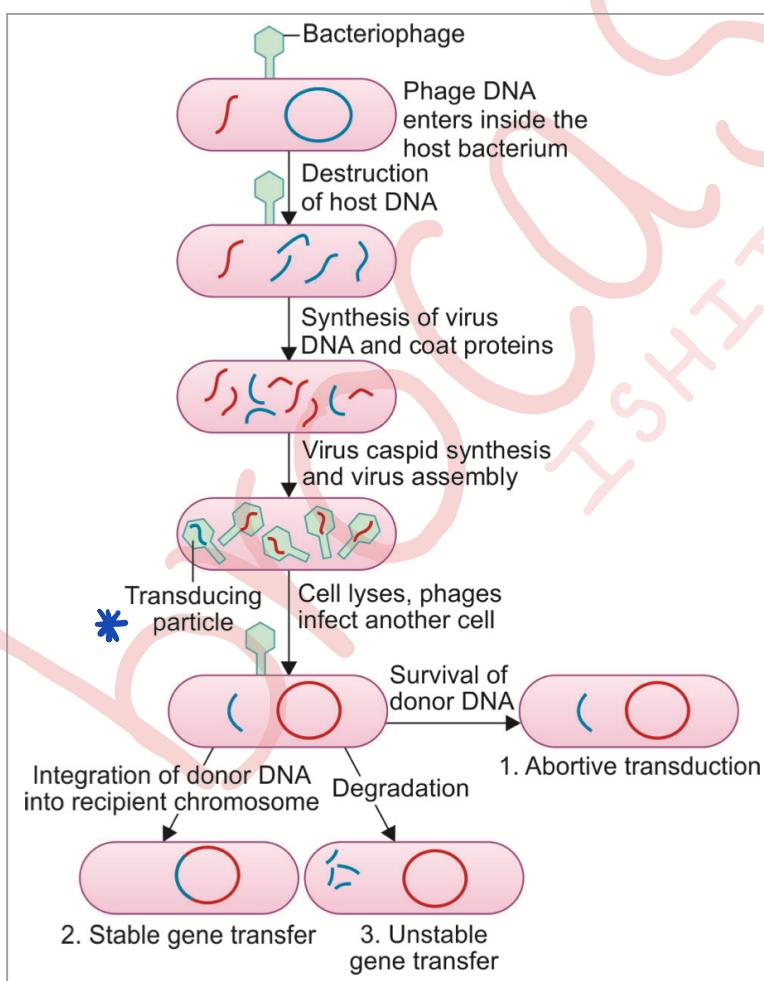

# Mechanisms of Gene Transfer in Bacteria:

- Transduction
- Lysogenic conversion
- Transformation
- Conjugation

} via phages

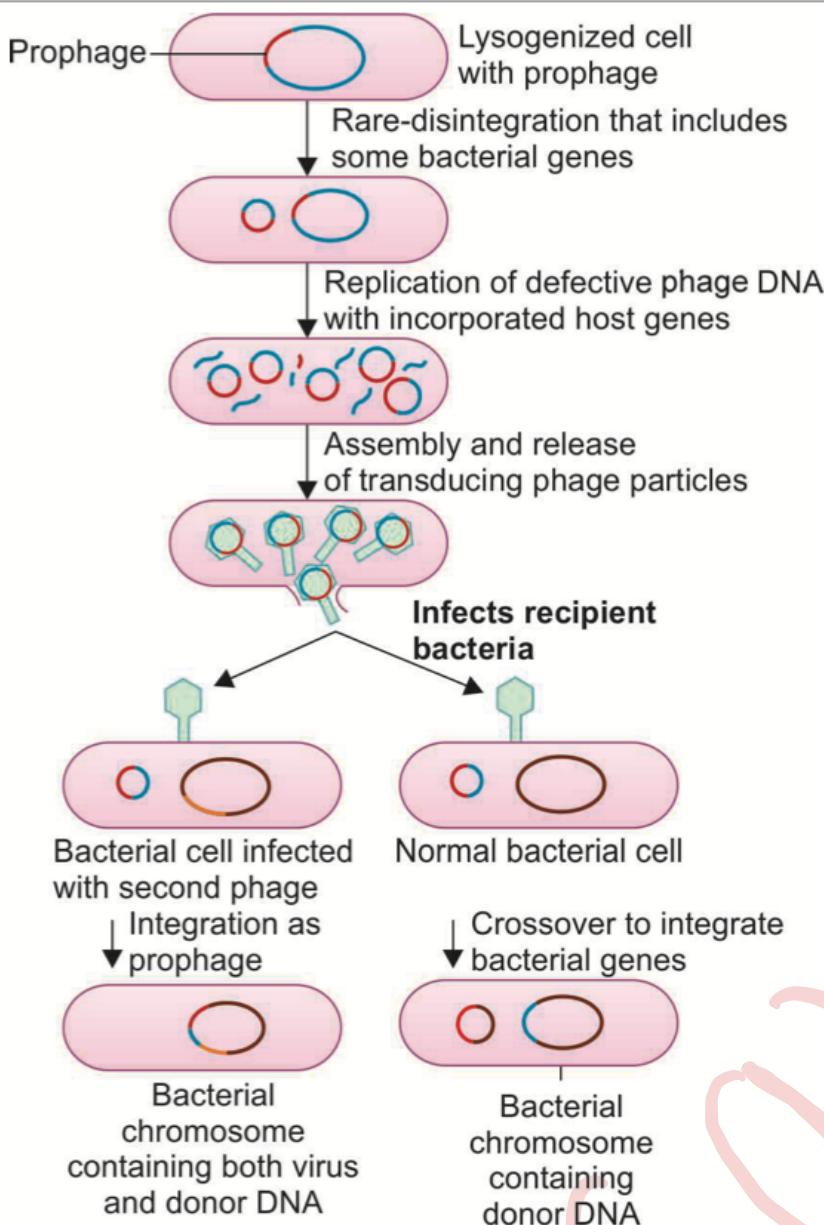

Transduction: transfer of bacterial genes from one bacterium to the other via phage

- most common mechanism of gene transfer in bacterium
- 1st demonstrated on Salmonella typhimurium.
- Transduction types:
  - Generalised
  - specialised

\* mis-packaging of bacterial chromosome fragment into newly synthesized phage.

Fig. 3.4.5: Generalized transduction.

→ only restricted / specific genes of bacterium that are next to the site of integration of phage DNA are incorporated into newly synthesized phages.

**Fig. 3.4.6: Restricted transduction / Specialized transduction**

### Generalized

- occurs in lytic cycle
- occurs due to mispackaging of chromosomal / plasmid genes during assembly
- mediated by virulent or temperate phage

### Specialized

- occurs following a lysogenic cycle
- occurs due to defective excision during induction of prophage
- mediated only by temperate phage

## Lysogenic Conversion :

→ prophage genes (in a lysogenic cycle) themselves provide genes for a new characteristic/phenotype to the lysogenic bacterium.

→ phage-mediated toxins

Ex: ability to produce toxins by bacteria

- *Corynebacterium diphtheriae*
  - non-toxigenic
  - toxigenic

## Phage Mediated Toxins :

A - Pyrogenic toxin A & C of *Streptococcus pyogenes*

B - Botulinum toxin C & D

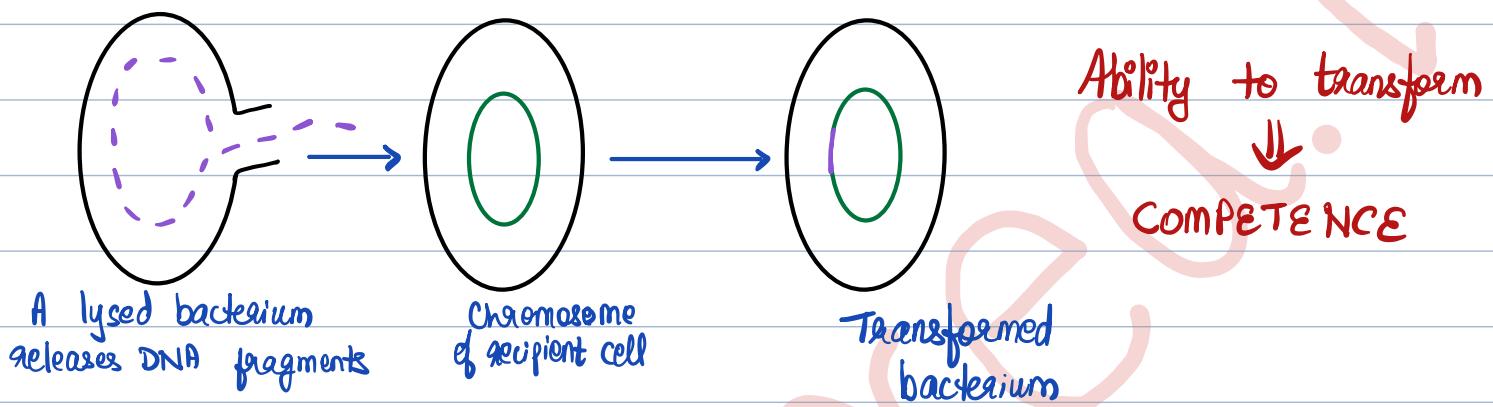

C - Cholera toxin

D - Diphtheria toxin

S - Shiga-like toxin / Verocytotoxin (produced by enterohemorrhagic *E. coli* - EHEC)

Transformation: uptake of soluble DNA fragments in the environment directly through the cell wall

ISHITA  
KANODIA

→ first demonstrated on *Streptococcus pneumoniae* by Griffith

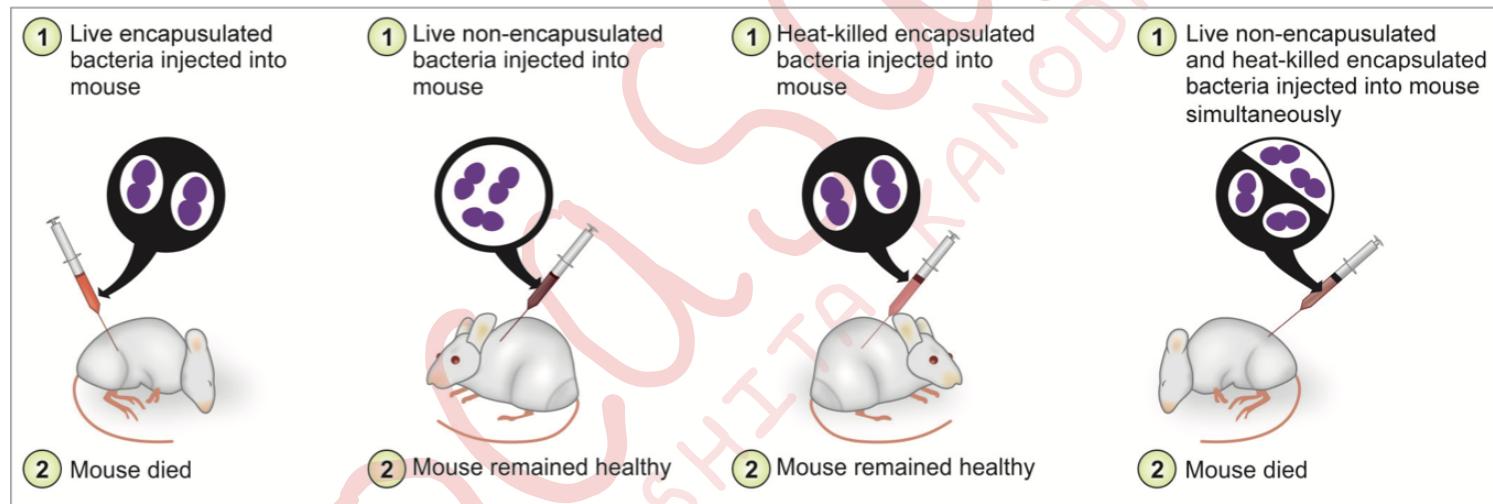

Fig. 3.4.4: Griffith experiment demonstrating transformation.

# Conjugation:

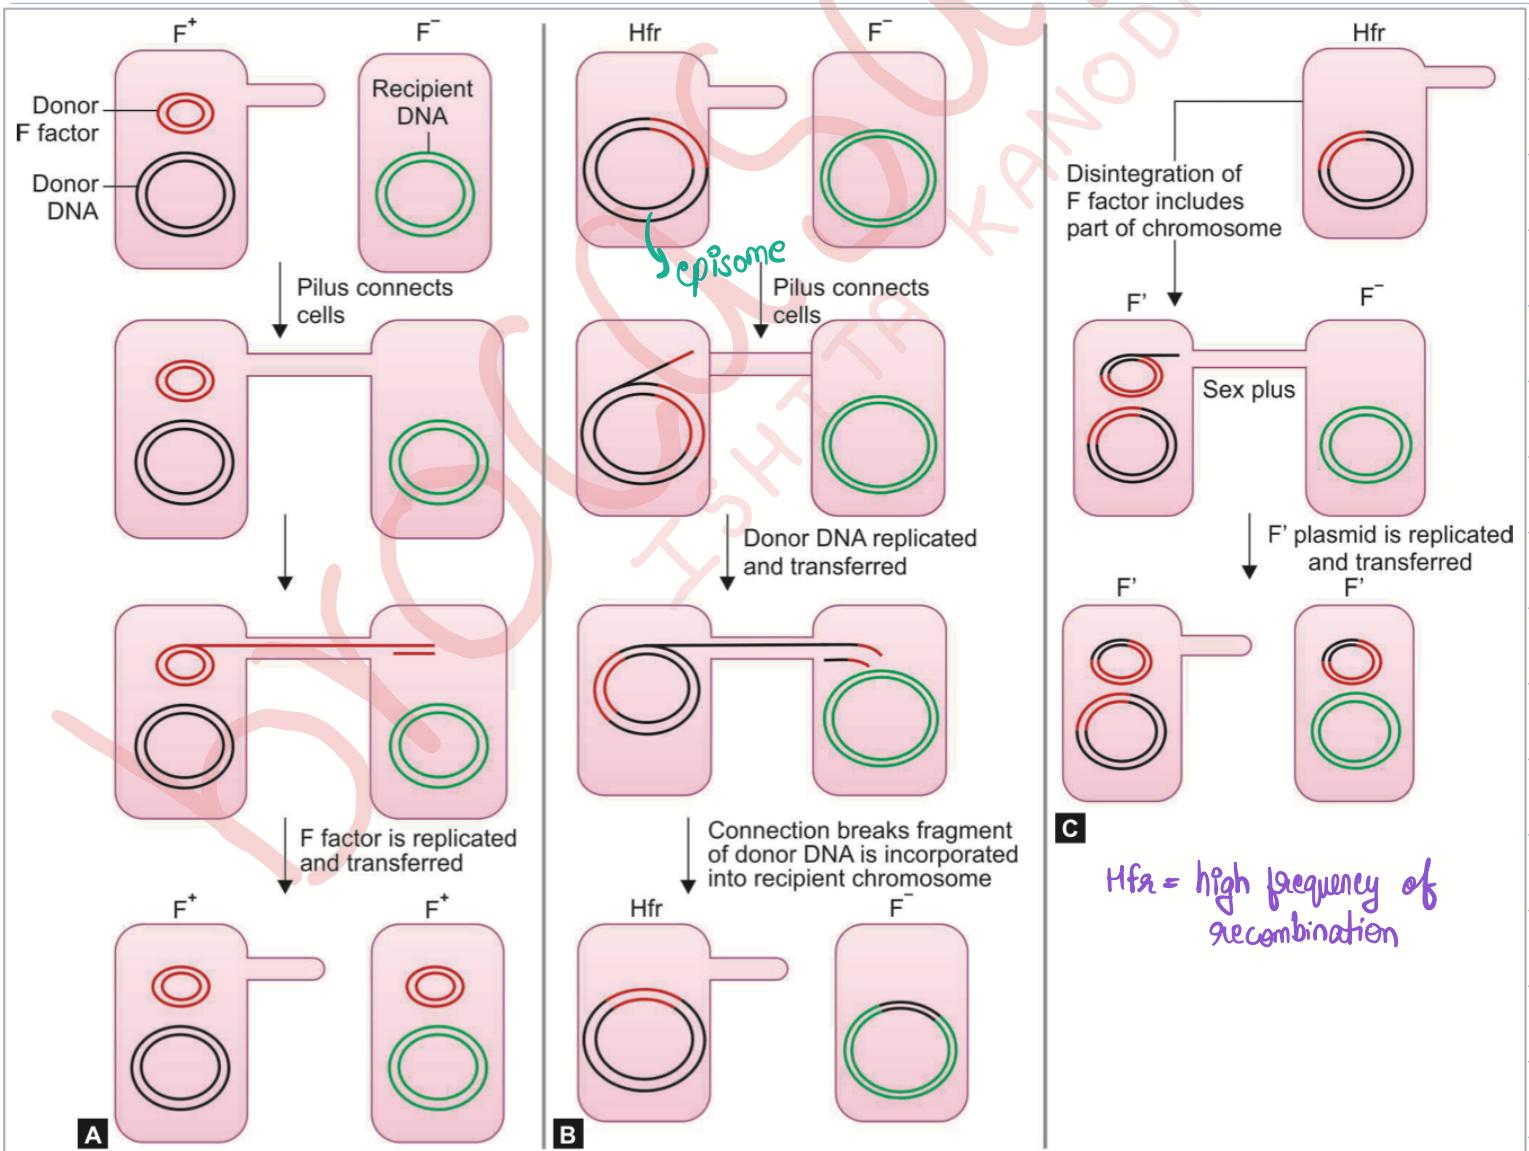

→ first demonstrated by Lederberg & Tatum on *E. coli* K12.

→ formation of sex pilus / conjugation tube

|| encoded by

F- plasmid / fertility plasmid /  
Sex plasmid / transfer factor.

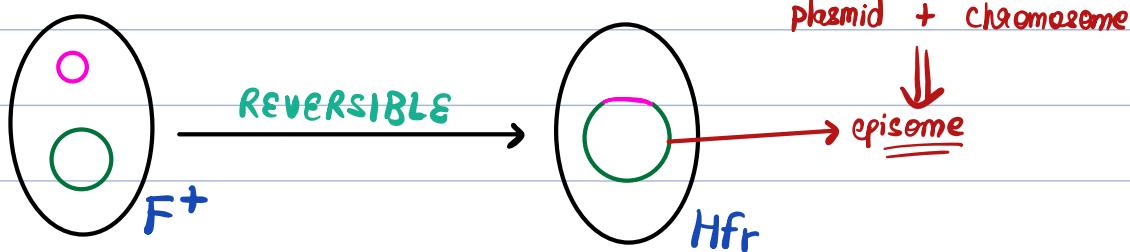

→ Bacteria which have F- plasmid  $\Rightarrow$  F+ bacteria  
" " don't " " "  $\Rightarrow$  F- "

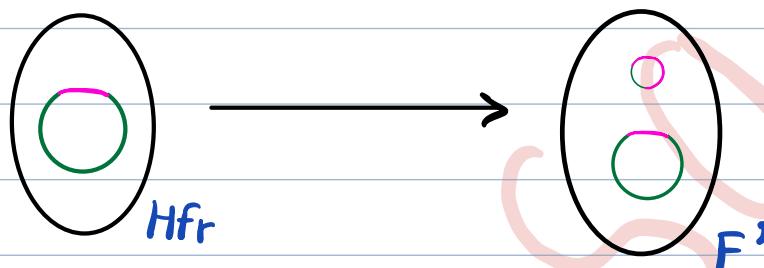

Figs 3.4.7A to C: Bacterial conjugation: **A.** F<sup>+</sup> X F<sup>-</sup> mating; **B.** Hfr X F<sup>-</sup> mating; **C.** F' X F<sup>-</sup> mating.

Hfr = high frequency of recombination

## Conversion of $F^+$ to Hfr

→ When the F plasmid reverts from integrated to free state, it may sometimes carry with it some chromosomal DNA from adjacent site of attachment. This F factor carrying some chromosomal DNA =  $F'$

TRANSFER OF  $F'$  PLASMID = "SEX DUCTION".

R-Plasmid: F plasmid + AB resistance genes

↓  
Called resistance transfer factor

↓  
Called R-determinant.

Most common mode of spread of antibiotic resistance in bacteria

→ first demonstrated in *Shigella*.

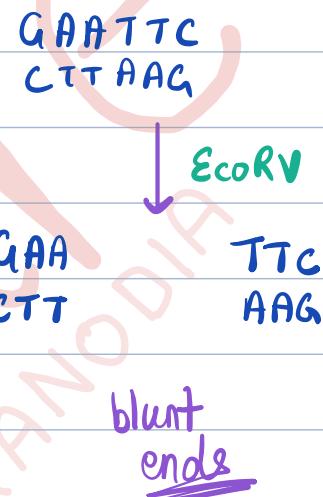

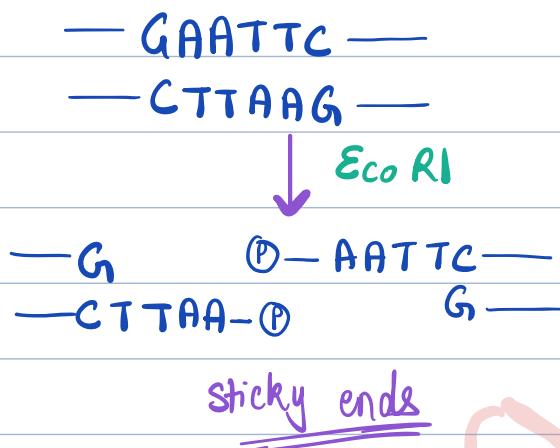

Col plasmid: F- plasmid + Bacteriocin genes

Restriction Enzymes/Endonucleases: produced by bacteria

Recognition sequence  $\Rightarrow$  can be palindromic or non-palindromic

Restriction site  $\Rightarrow$  may be a part of the recognition sequence or it may be several nucleotides away

Sticky ends }  
Blunt ends }

→ Restriction endonuclease is a defence mechanism in bacterial systems against foreign DNA.

— But, its own DNA is protected from digestion by endonuclease due to methylation of bacterial DNA by restriction enzyme [Restriction Modification Systems]

→ Type II restriction enzymes cut within recognition sites

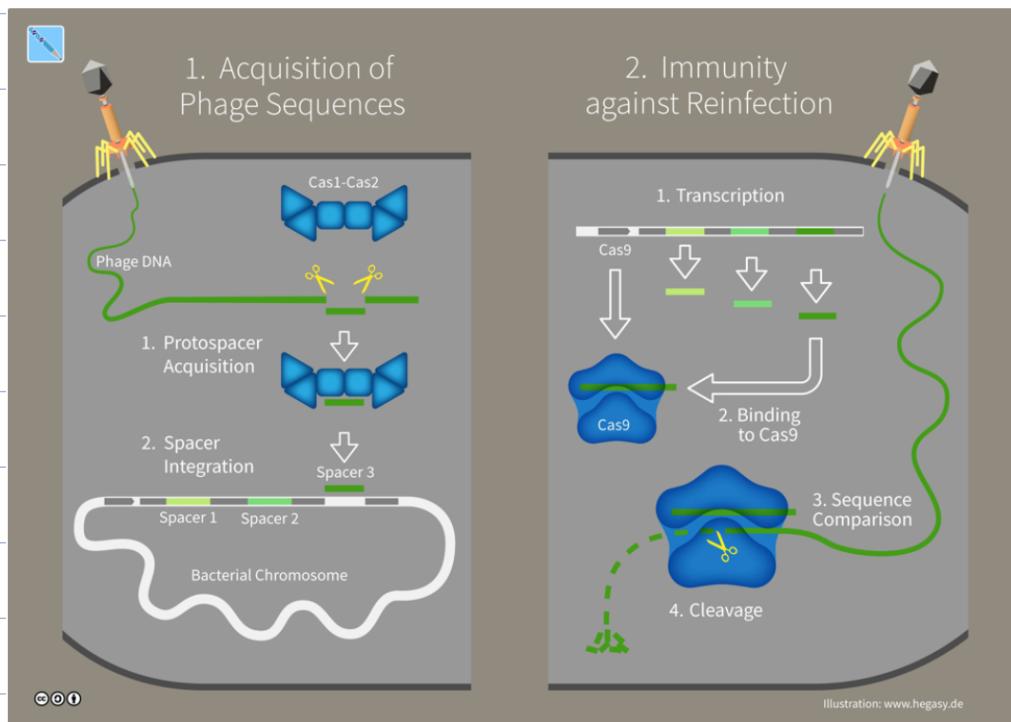

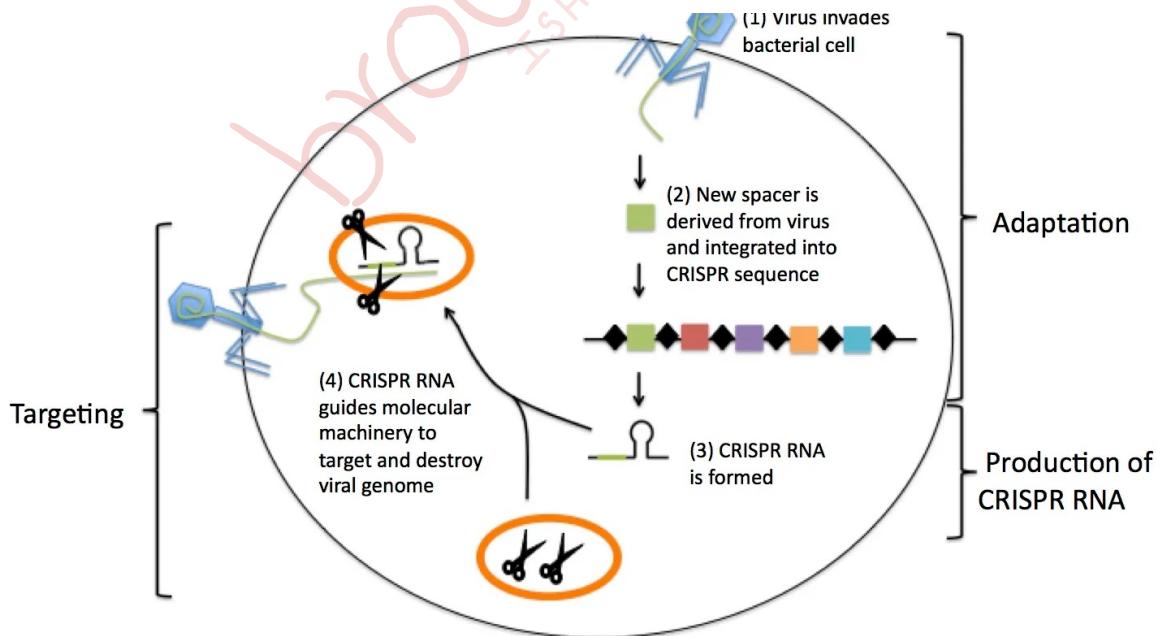

→ all REs require  $Mg^{+2}$  cofactor.

# CRISPR [clustered Regularly Interspaced Short Palindromic Repeats]:

- considered as an adaptive immune response of bacteria
- bacterial genome editing method to protect from infecting viruses

R = repeat

S = spacer

# Typing of Bacteria: intraspecies characterization of various strains

↪ used in epidemiologic studies.

## • PHENOTYPIC METHODS

- Serotyping (*Streptococcus pneumoniae*)
- Biotyping (*Hemophilus influenza*)
- Antibogram typing
- Bacteriisin typing
- Phage typing
- Whole cell protein Electrophoresis
- Multilocus Enzyme Electrophoresis

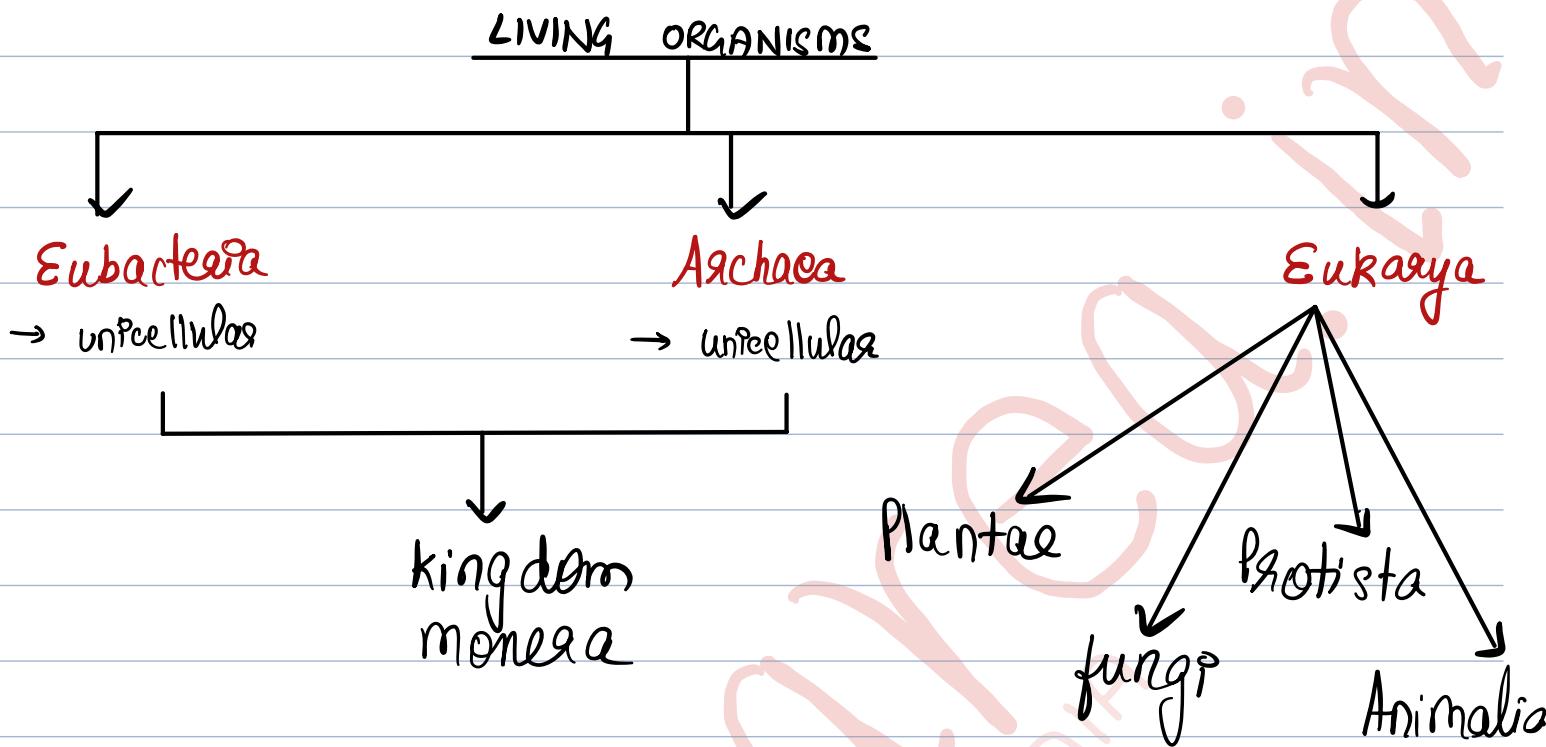

## • GENOTYPING METHODS

- Plasmid profile analysis (PFGE)
- Pulsed field gel electrophoresis
- Restriction Fragment Length polymorphism
- Ribotyping (RFLP)
- Nucleic acid sequencing

# Anatomy & Physiology of Bacteria:

	Prokaryotes	Eukaryotes
Nucleus	<u>Nucleoid</u> - no well defined nuclear membrane - nucleolus absent - histones absent	- well defined nuclear membrane
Chromosomes	• Single circular (ds DNA) plasmids	• Multiple linear present in mitochondria
Extra-chromosomal DNA	mostly absent	all present
Membrane-bound organelles		

	Prokaryotes	Eukaryotes
Cell Wall	Muramic acid present	No muramic acid in cell wall / complete absence of cell wall.
Cell Membrane	Stegols absent	Stegols are present
Ribosomes	70s	80s
Mesosomes	present $(g_{+ve} > g_{-ve})$ .	absent

### EXCEPTIONS:

- Prokaryote lacking cell wall is **Mycoplasma**  
∴ highly plasmophilic known as jumping jacks of microbes
- Prokaryotes having stegols in cell membrane : **Mycoplasma**
- Prokaryotes having 2 chromosomes  $\Rightarrow$  **Vibrio**
- Prokaryote that lacks muramic acid in its cell wall: **Chlamydia**.

Archaea: non-pathogenic bacteria

a.k.a Extremophiles (can survive extreme conditions)

Ex: Thermus aquaticus.

### Eubacteria

→ peptidoglycans in cell wall are present

- absent

→ introns are always absent

- absent

• Eubacteria

• Cyanobacteria (blue-green algae)

### Archaea

→ absent

helps them survive in extreme conditions

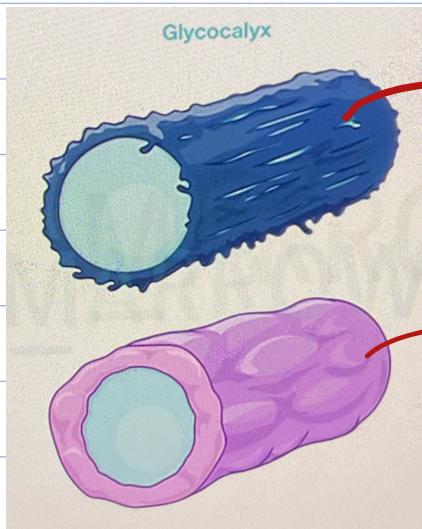

- presence of isoprenoid lipids in cell membrane

→ introns are present in some genes

- characteristic rRNA sequences present

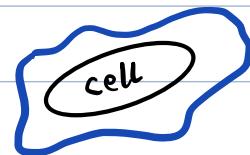

Glycocalyx: layer around the cell wall

→ may or may not be present

Slime: loose, ill-defined polysaccharide layer

→ group of bacteria growing together ⇒ slime collects & forms

### BIOFILMS

- helps in adhesion
- anti-phagocytic
- reduces the entry of antibiotics

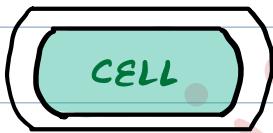

Eg: • *Streptococcus mutans*

- *Pseudomonas aeruginosa*
- *Staphylococcus epidermidis*

Capsule: well-defined layer around the cell wall

→ generally polysaccharide in nature

EXCEPT • *Bacillus anthracis* } poly peptide  
• *Yersinia pestis* } capsule

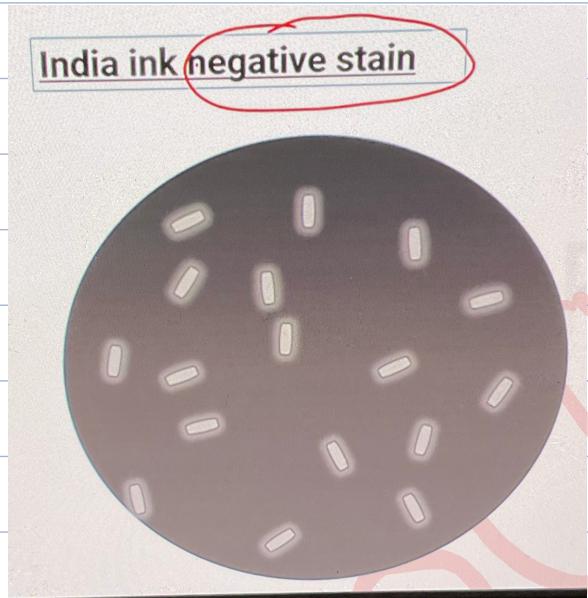

→ capsule is anti-phagocytic

→ it has no net charge

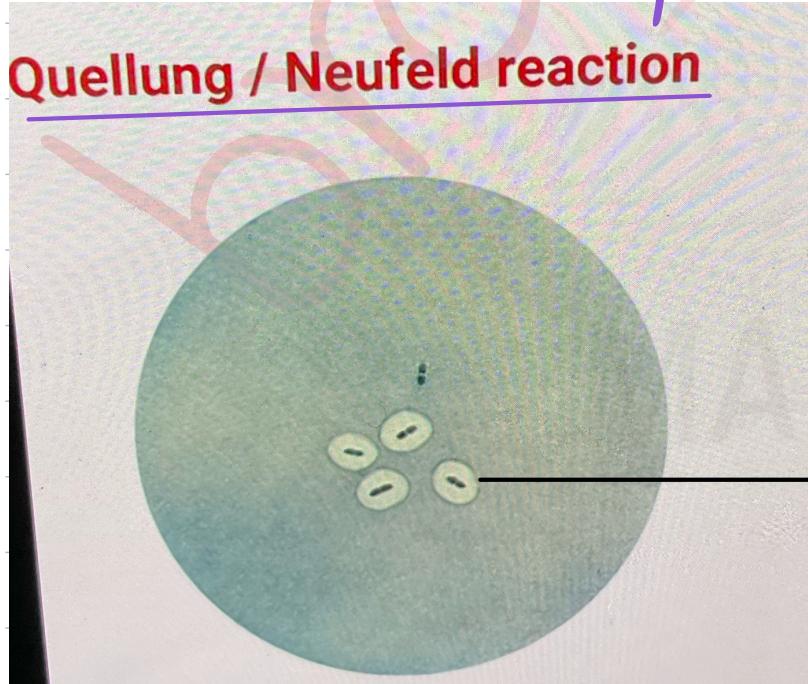

∴ cannot be gram stained

→ Capsule stains: Copper salts

(India ink or Nigrosine)

→ used for capsular typing of bacteria.

Capsule is antigenic  
∴ it produces Ab's

Capsule + Anticapsular Ab's

→ Swelling of capsule

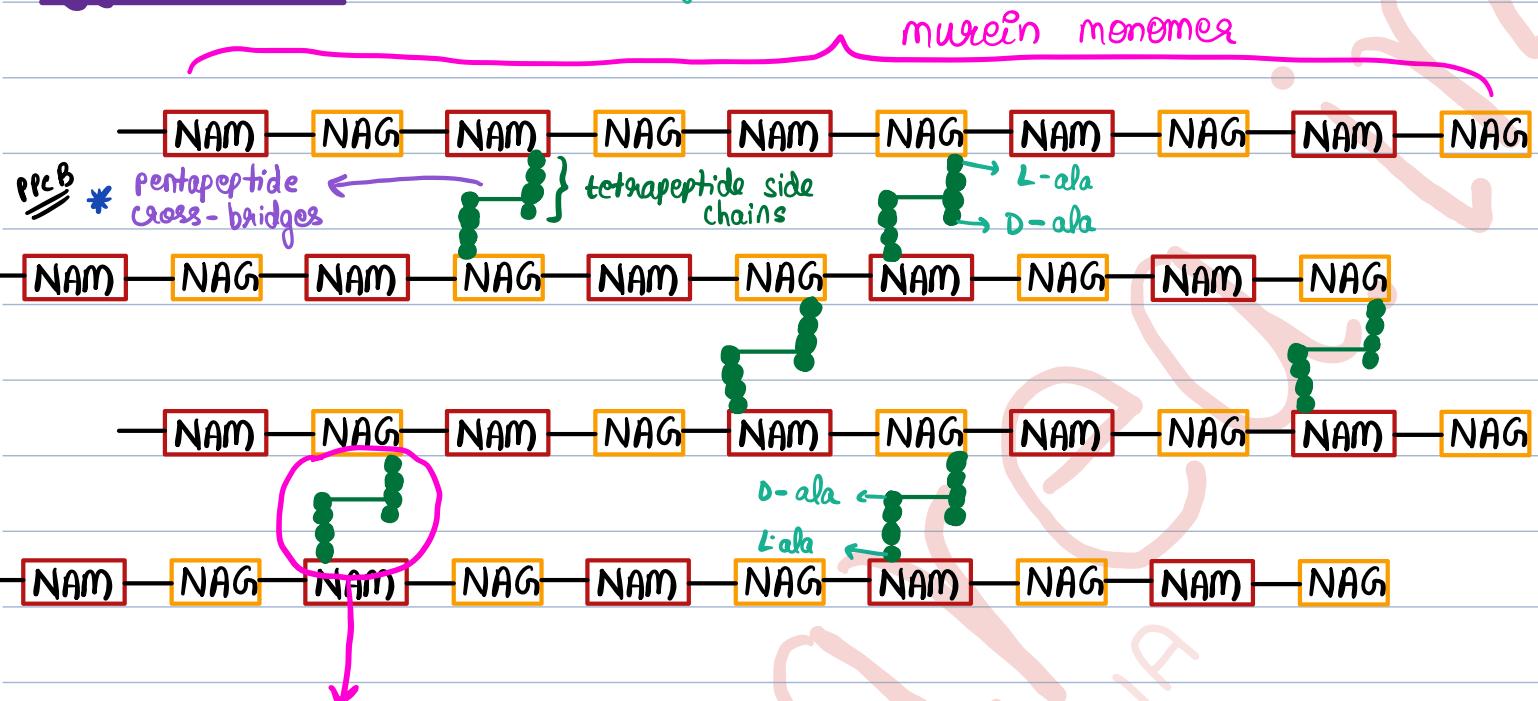

Yes Some Bacteria Have Very Killer And Mean Capsules

- *Yersinia pestis*  $\Rightarrow$  polypeptide capsule
- *Streptococcus pneumoniae*
- *Staphylococcus aureus*  $\Rightarrow$  microcapsule (very thin), zwitter ionic
- *Bordetella pertussis*  $\Rightarrow$  Non- antigenic capsule
- *Bacteroides fragilis*  $\Rightarrow$  zwitter ionic capsule
- *Haemophilus influenzae*
- *Vibrio parahaemolyticus*
- *Klebsiella pneumoniae*
- *Bacillus anthracis*  $\Rightarrow$  polypeptide capsule
- *Meningococcus*
- *Clostridium perfringens*  $\Rightarrow$  most common cause of gas gangrene
- *Cryptococcus*  
(fungus)  
neoforans  
gattii

## Cell Wall:

NAG = N-acetyl glucosamine

NAM = N-Acetyl muramic acid

## CROSS-LINKING ENZYMES IN BACTERIA:

- Transpeptidases
- Transglycolases.

all  $\beta$ -lactam antibiotics bind to transpeptidases

inactivation of transpeptidases

aka Penicillin Binding Proteins.  
(PBPs)

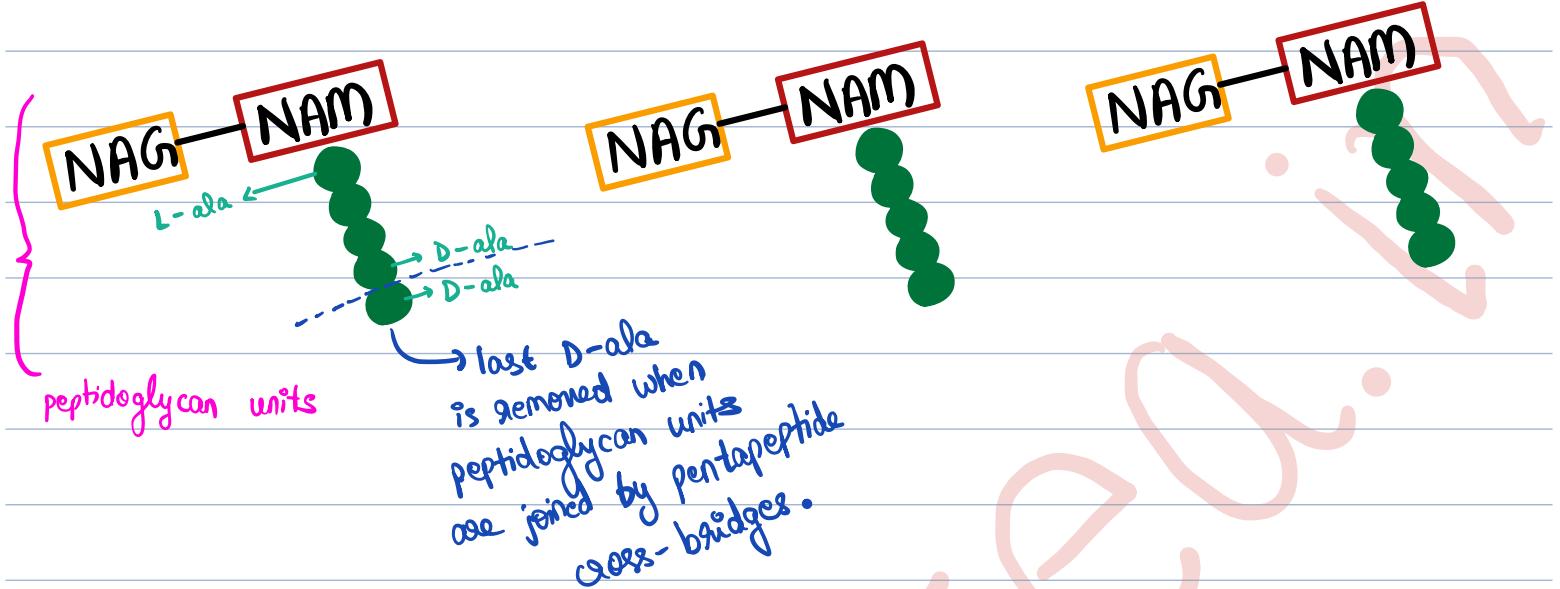

## inactivation of transpeptidases

no - cross linking

## Impairment of cell wall synthesis

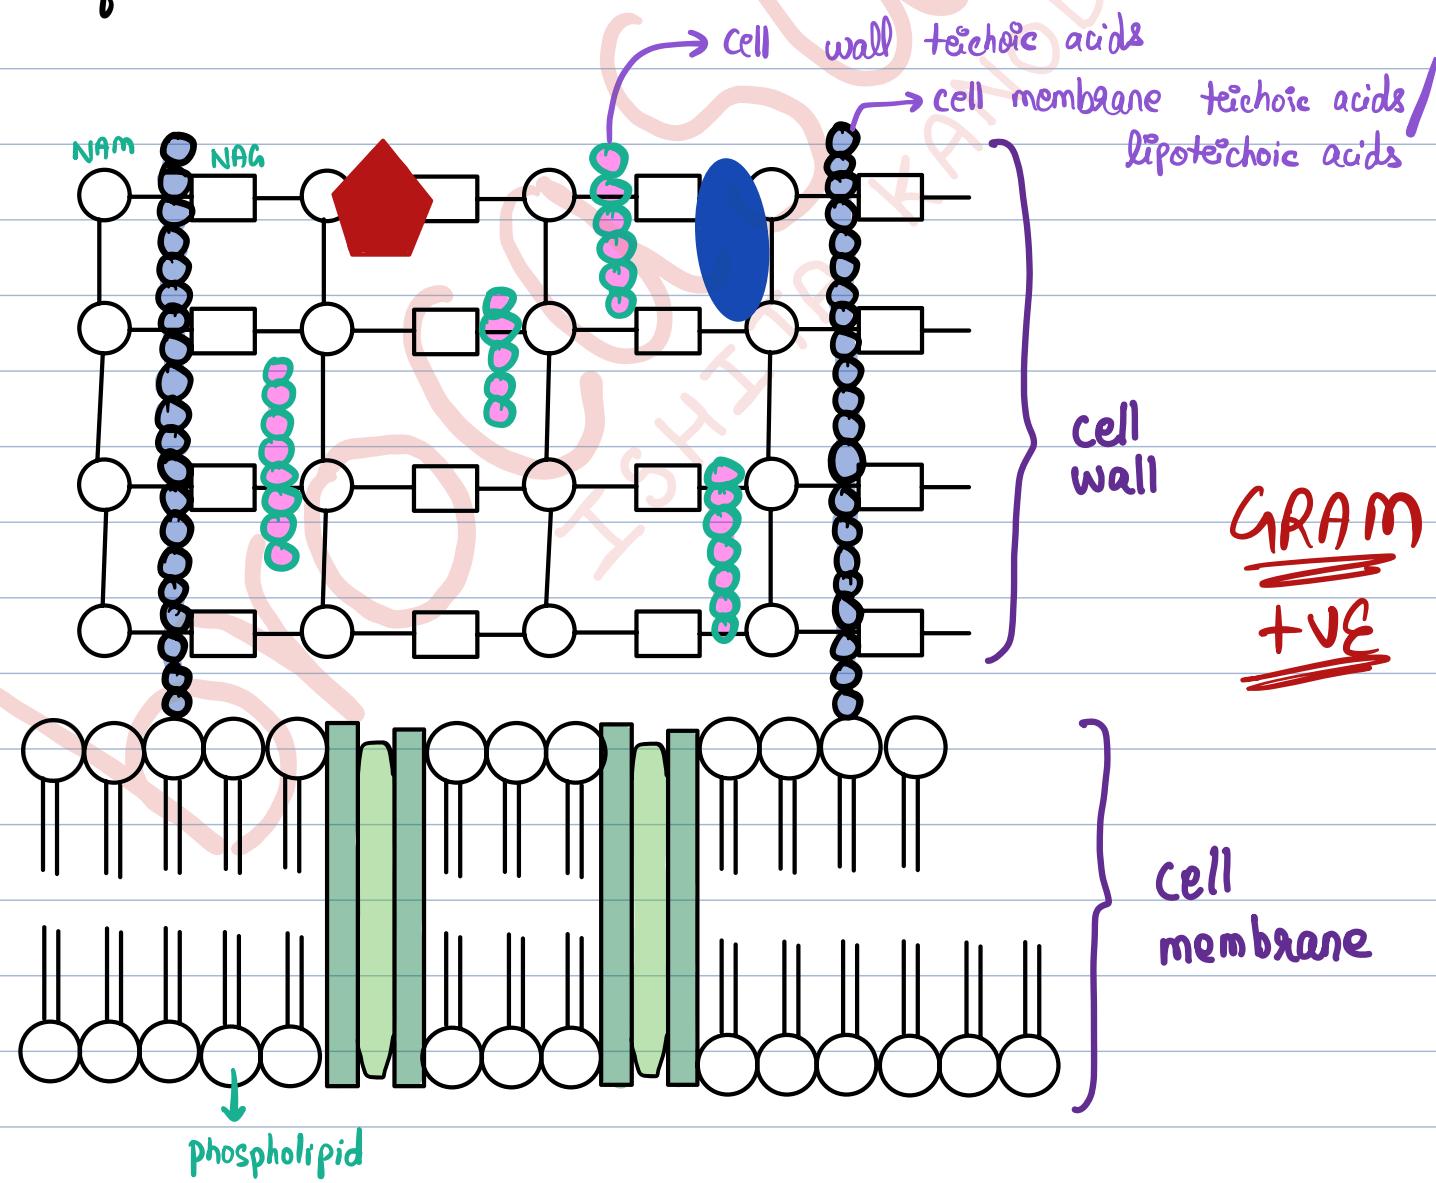

→ gram +ve cell wall has 50 - 100 layers of murein monomers

(\* between 3rd  $\bar{a} \cdot \bar{a}$  from one chain & 4th  $\bar{a} \cdot \bar{a}$  from another)  
[NAM/NAG] [NAG/NAM]

Vancomycin: binds to terminal D-alanine & prevents formation of PPGBs

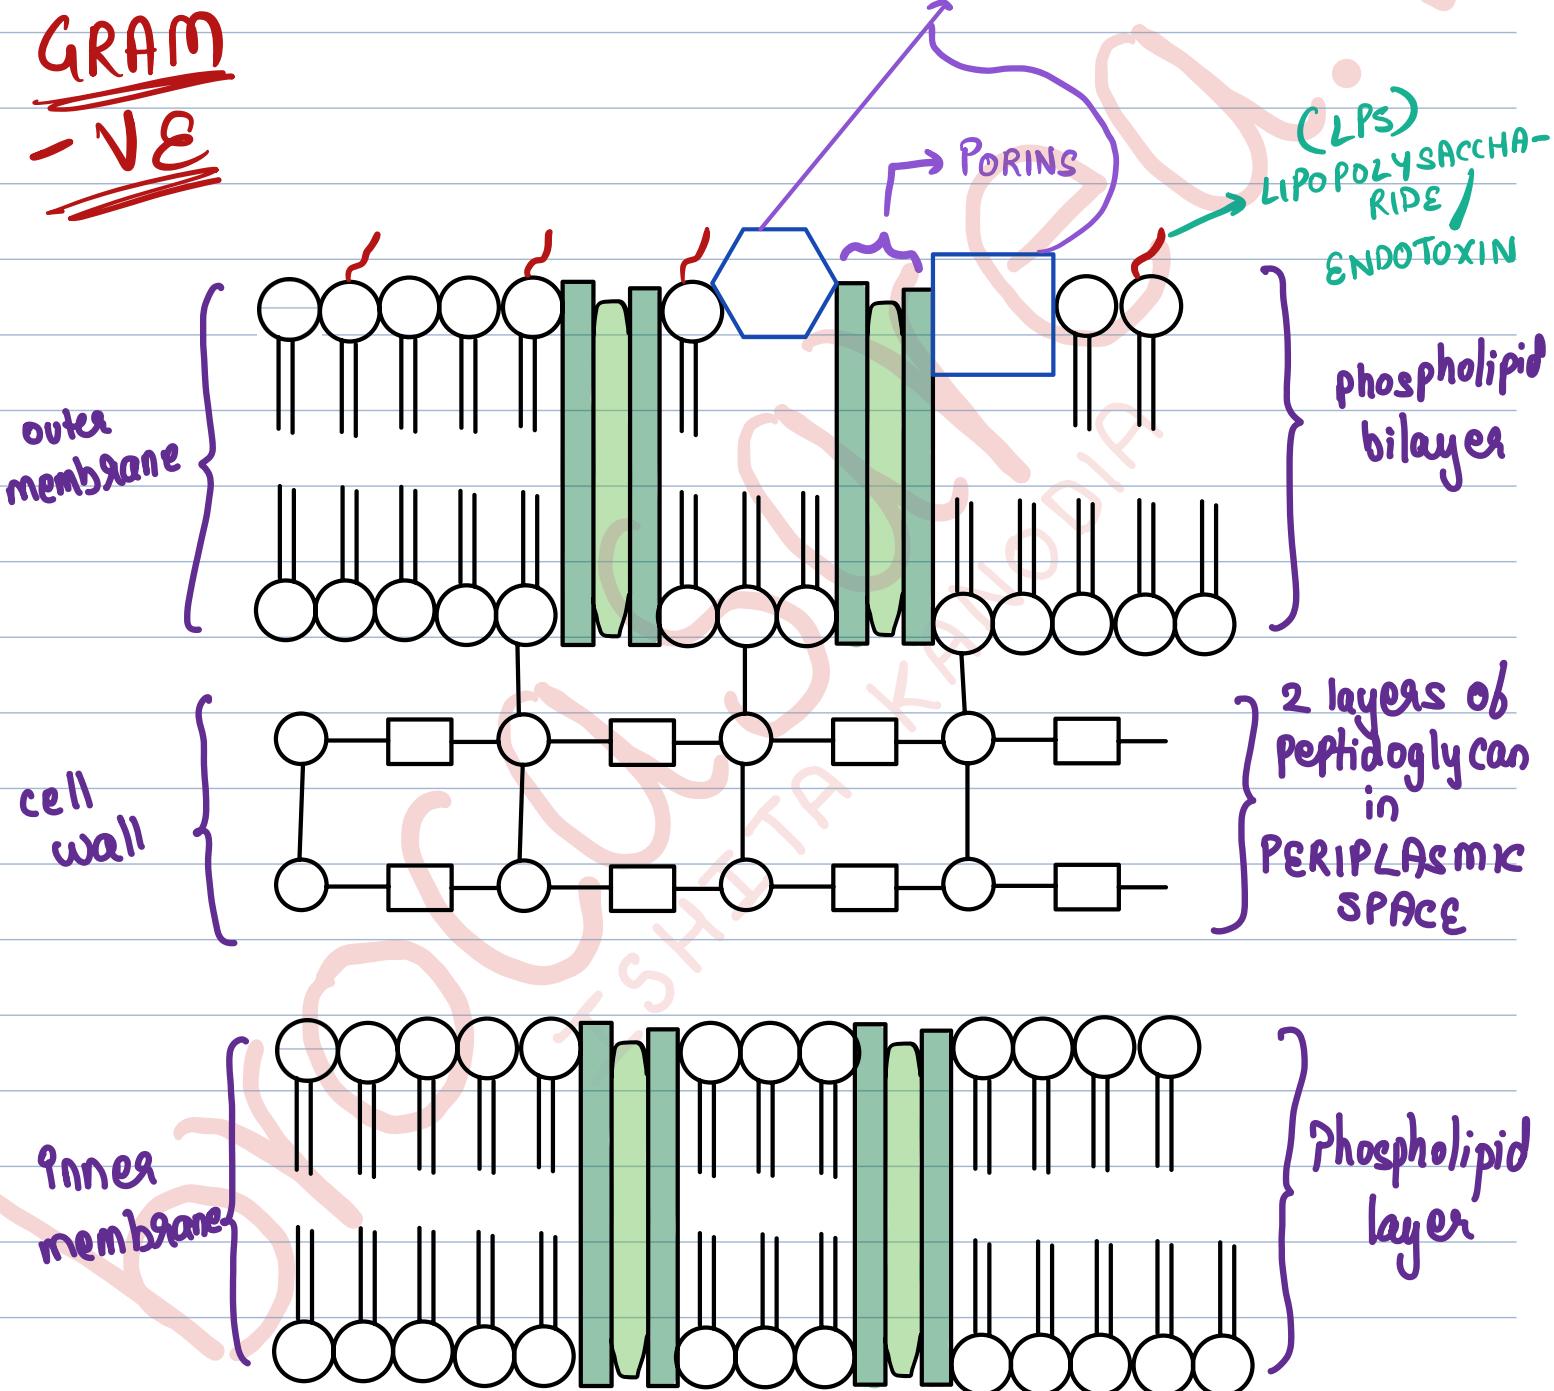

D-alanine & D-alanine  
(cell wall precursor)

- Cell wall teichoic acids: polymers of ribitol phosphate.
- cell membrane teichoic acids: polymers of glycerol phosphate.
- Teichoic acids are said to have a role in adhesion

GRAM  
-IVE

### STRUCTURAL/INTEGRAL PROTEINS

→ Just above the phospholipid bilayer (cytoplasmic membrane) is a space known as the periplasmic space which contains the two layers of murein monomers linked by PPGBs

→ Outside this, is another phospholipid bilayer called outer membrane

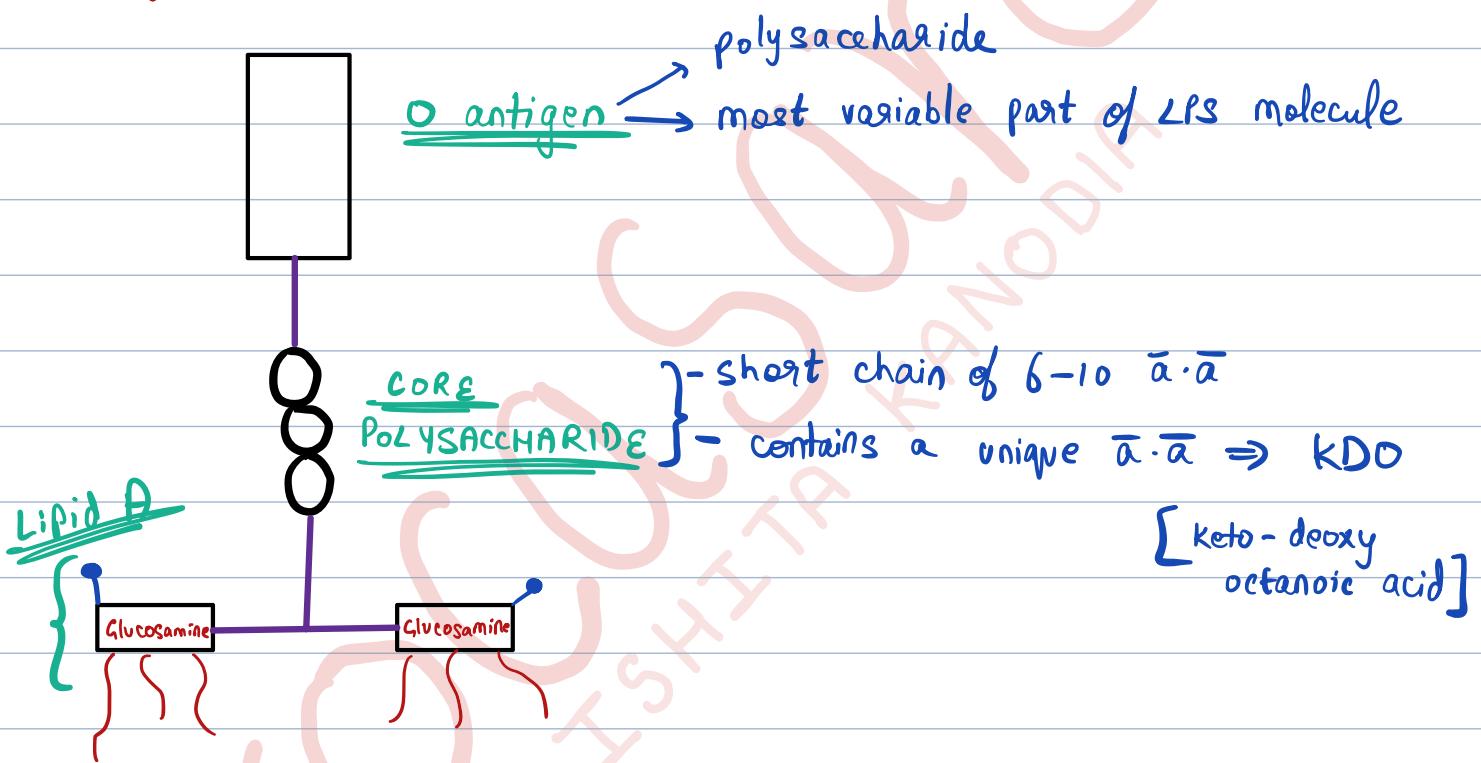

→ In the outer membrane, there are some special structures:

- i) Porins
- ii) Structural/integral proteins
- iii) Lipopolysaccharide (LPS) / Endotoxin  $\Rightarrow$  embedded in the outer leaflet of the outer membrane.

	Gram +ve cell Wall	Gram -ve cell wall
Thickness	$\sim 80\text{ nm}$	$10 - 25\text{ nm}$
Layers of peptidoglycan	$50 - 100$	2 (in periplasmic space)
Amino acids in peptidoglycans	Aromatic & sulphur containing $\text{--}\text{a}\text{--}\text{a}$ absent.	All $\text{--}\text{a}\text{--}\text{a}$ present
Tetrahydrofuran acids	Present	Absent
Outer membrane	Absent	Present
Lipid content	$5 - 10\%$	$30 - 50\%$

	Gram +ve cell Wall	Gram -ve cell wall
Porins	Absent	Present
LPS (Endotoxin)	Absent <u>Except</u> : <i>Listeria monocytogenes</i>	Present

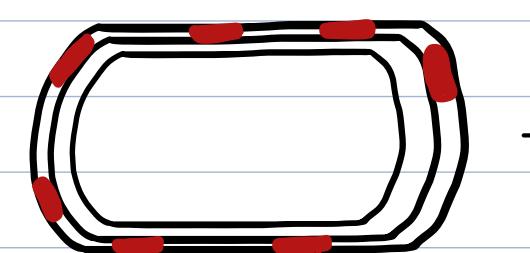

## LPS / Endotoxin:

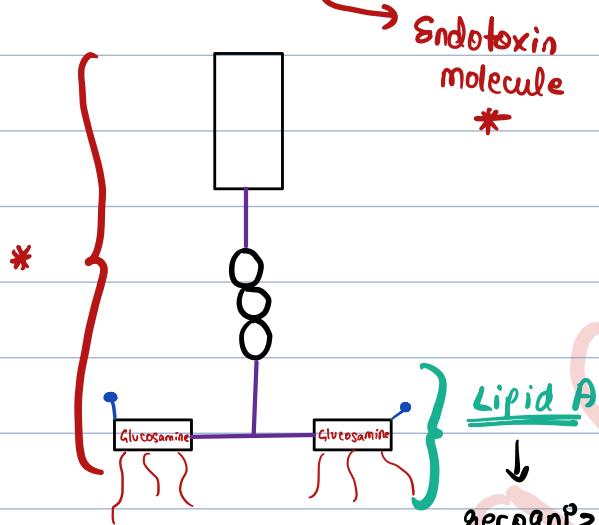

Lipid A: embedded in outer membrane

↳ responsible for the actual endotoxic activity

## Action of Endotoxin

→ Lysis

recognized by TLR-4 on dendritic cell & macrophages

Binding

↓  
Activation of Nuclear Transcription factor -  $\kappa\beta$

↓

cytokine release from

dendritic cell & macrophages

[IL-1,6 ; TNF- $\alpha$  ; IL-8,12]

# Effects of Endotoxin

Macrophage activation

Cytokine release from macrophages, dendritic cells

Fever, hypotension

Complement Activation

C3a & C5a

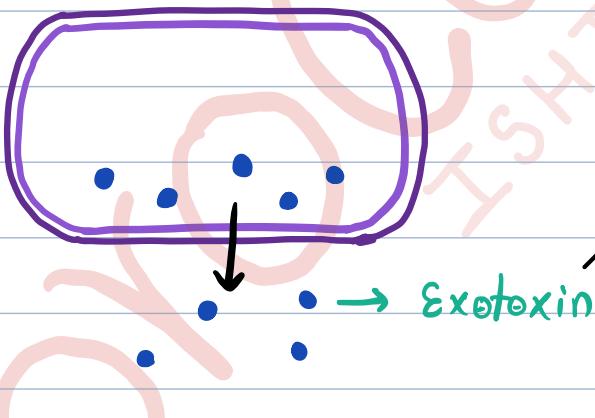

Histamine release

Neutrophil chemotaxis  
increased vascular permeability

Tissue factor activation

Activation of coagulation

DIC, Shock  
[disseminated intravascular coagulation]

proteins in nature

Eg: Botulinum toxin,  
Diphtheria toxin,  
Tetanospasmin

Endotoxin

- LPS
- Released only on lysis
- unique to gram -ve bacteria
- Heat stable EXCEPT: LISTERIA
- low antigenicity
- cannot be toxoided.
- needs to be present in large amounts to mediate their action in humans.
- CONSTANT EFFECTS

Exotoxin

- Protein
- actively secreted Except: Botulinum
- produced by both gram -ve & +ve
- Heat labile Except: Staph. aureus & bacillus cereus emetic toxins
- highly antigenic.
- can be toxoided.
- (toxin which has lost its virulence, but can still induce antibodies)
- even small amounts can mediate their action.
- VARIABLE EFFECTS in humans.

Lipopolysaccharide Amebocyte Lysate (LAL) Assay:

↓  
Horse-shoe crab  
 +  
 drop of clinical specimen (endotoxin)  
 ↓  
 gelling of lysate

→ sensitive assay for endotoxin (LPS) assay.

## L forms: cell wall deficient bacteria

- first discovered by Kleinberger Nobel at Lister Institute on Streptobacillus moniliformis.
- can be formed by both gram +ve & -ve bacteria
- they are either formed spontaneously or in the presence of cell wall inhibitors (like penicillin) or in the presence of lysozyme.  
break the bond b/w NAM & NAG.

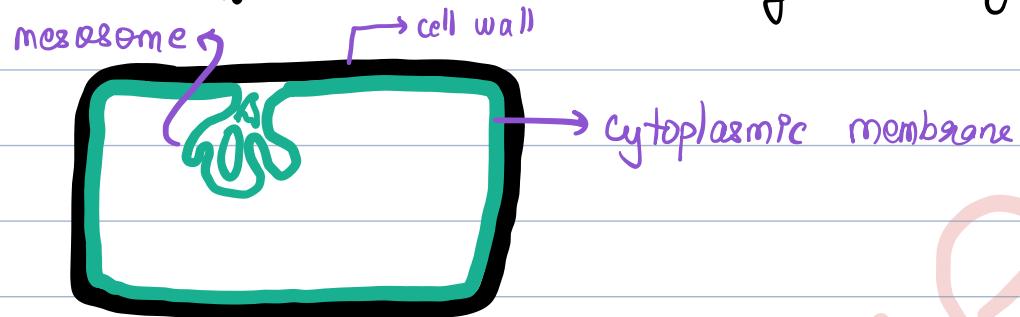

• Gram +ve + lysozyme → PROTOPLAST  
(L-form of gram +ve bacteria)  
in osmotically protected medium

• Gram -ve + lysozyme + EDTA → Spheroplasts.  
(L-form of gram -ve bacteria)  
in osmotically protected medium

- L-forms can be cultivated on special media on which they form TINY COLONIES
- Non-pathogenic
- Two types:
  - Stable ⇒ remain cell wall deficient for the rest of their lives
  - Unstable ⇒ can revert back to their cell-walled status
- Can be responsible for persistence of infections & recurrence/relapse of infections.

# Mesosomes : invaginations of cytoplasmic (cell) membrane

- sites for respiratory enzymes
- site at which bacterium undergoes binary fission.

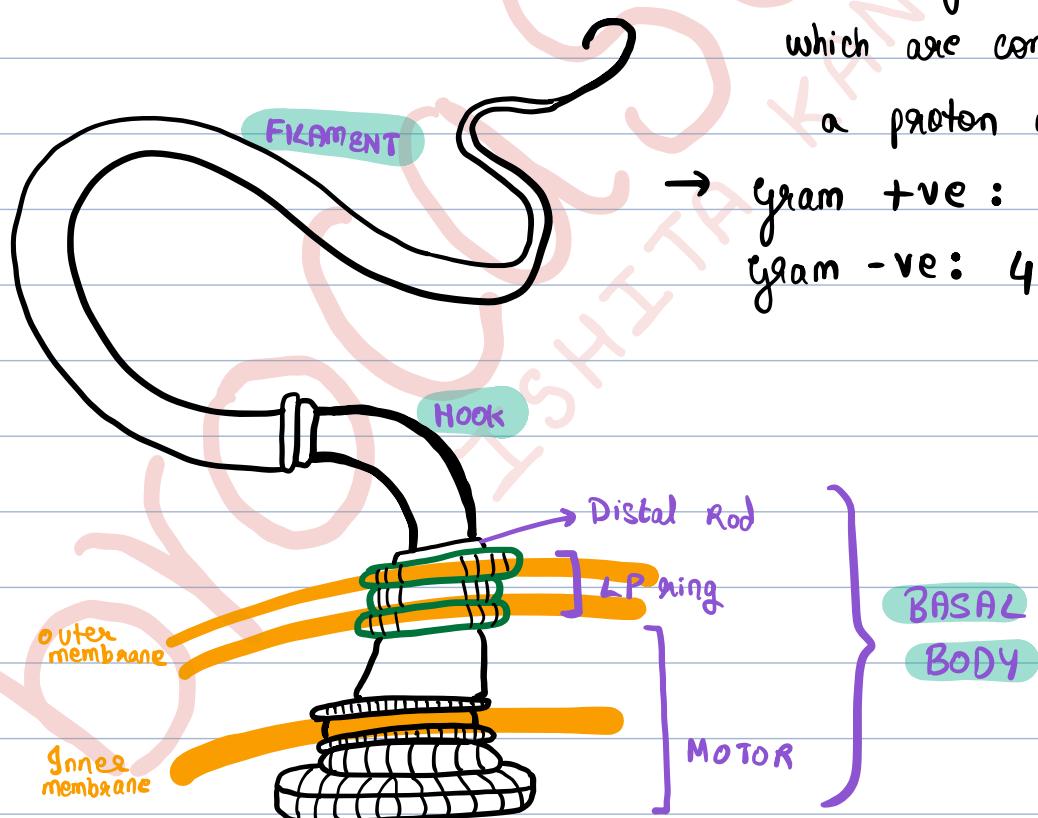

- gram +ve have more mesosomes than gram -ve.

# Flagellum:

- helps the bacteria in locomotion
- composed of protein subunits called flagellin.
- highly antigenic
  - Flagellum antigens = H- antigen
  - corresponding Ab = H-Ab.
- Length: 3 - 20  $\mu\text{m}$
- Thickness: 0.01  $\mu\text{m}$
- ∴ flagella are too slender to be seen by light microscopy.

## Flagellum Structure:

- Basal body is made up of rings which are constantly rotated by a proton dependent pump.
- gram +ve: 2 rings  $\rightarrow$  M, S  
gram -ve: 4 rings  $\rightarrow$  M, S, P, L

## Flagellum Distribution:

→ MONOTRICHUS

- Vibrio

- Pseudomonas

→ LOPHOTRICHUS

- Helicobacter

- Campylobacter  
(sometimes)

AMPHITRICHUS

- COMPYLOBACTER
- SPIRILLUM

### PERITRICHUS

form only at room  
temperature (25-28°C)

- Enterobacteriaceae
- Bacillus

- Clostridium
- Listeria

### ATRICHUS

- All pathogenic cocci are atrichus.

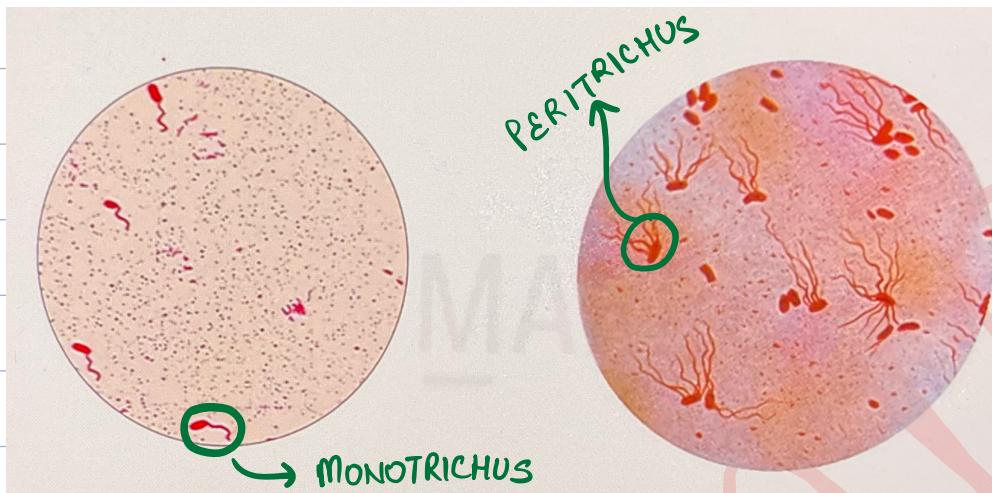

Endoflagella: flagella in periplasmic space

- Spirochetes

## Flagellum Demonstration:

Direct Methods: • Electron microscope

• Leifson & Ryu's impregnation stain

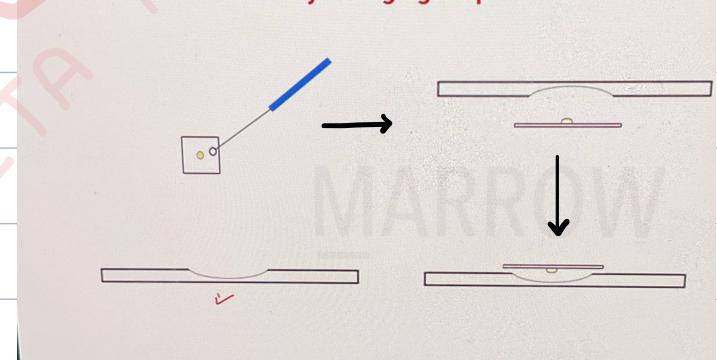

Indirect Methods: • Checking motility

### Demonstration of Motility:

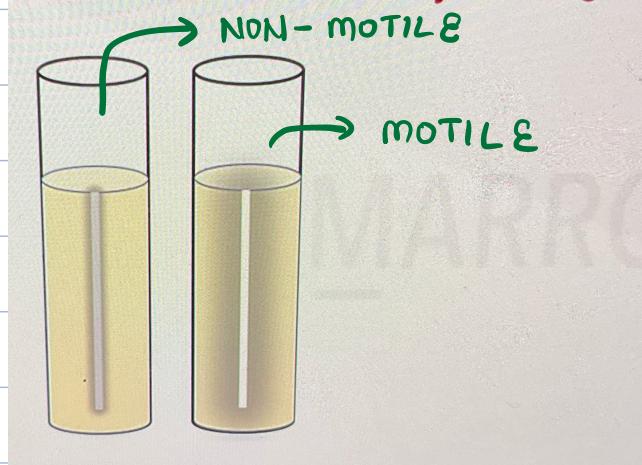

- ① Wet mount
- ② Hanging drop preparation
- ③ Soft Agar Medium.  
(0.2-0.5% agar)

stab inoculate  
addition of TTC \*

Demonstration of motility- Hanging drop

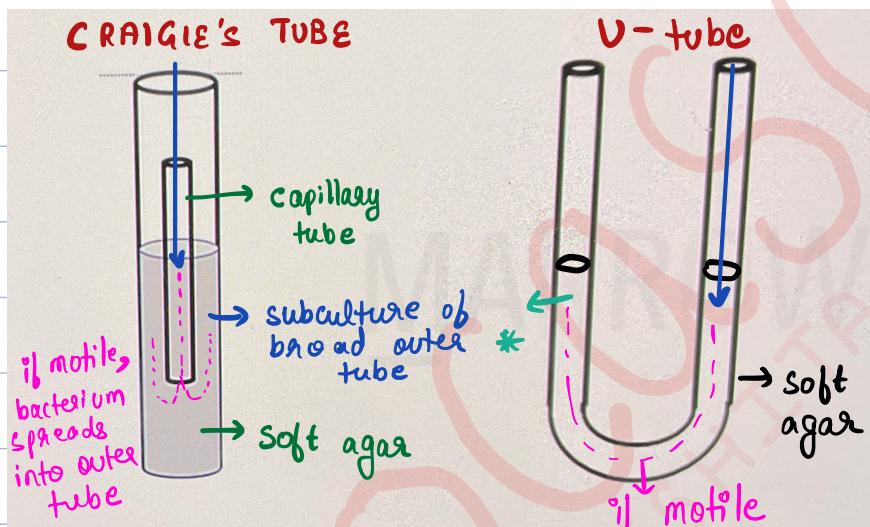

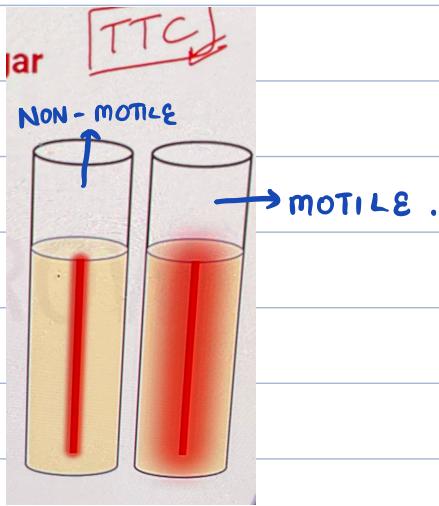

Demonstration of motility- Soft agar

## \* TTC [Triphenyl tetrazolium chloride]

↳ changes colour when it comes across bacterial metabolites.

\* Subculture from opposite end after overnight incubation

## Types of Motility :

- **Corkscrew** : *Treponema pallidum*
- **Darting / Shooting star** : • *Vibrio* • *Campylobacter*
- **Gliding** : *Mycoplasma*
- **Stately** : • *Salmonella* • *Clostridium*
- **Tumbling / End-on-End** : *Listeria*
- **Twitching** : *Escherichia coli*

Swarming : phenomenon seen on blood agar plate

→ Swarming can be prevented by the use of FIRM AGAR (5-6% agar).

Examples :

Gram +ve : - *Clostridium tetani*

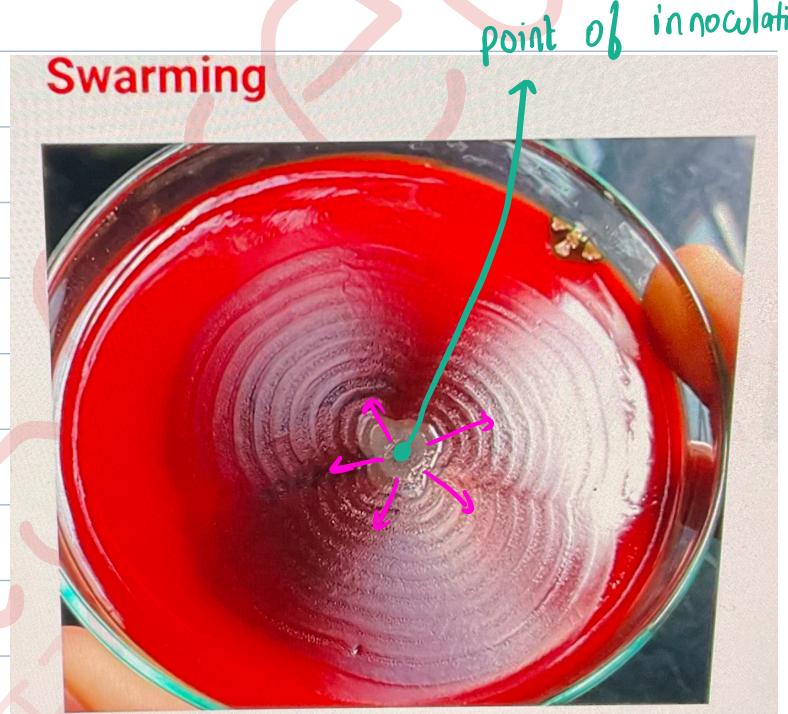

- *Bacillus cereus*

Gram -ve : - *Proteus vulgaris*

- *Proteus mirabilis*

- *Vibrio alginolyticus*

- *Vibrio parahaemolyticus*.

## Differential Motility :

→ motile at room temperature ( $25-28^{\circ}\text{C}$ )

→ non-motile at  $37^{\circ}\text{C}$

- *Listeria*
- *Yersinia enterocolitica*
- *Yersinia pseudotuberculosis*

## Pilli / Fimbriae :

→ made of repeating protein subunits : Pilin

→ shorter than flagella

### ① Common Pili : help in adhesion

↳ present only on gram -ve bacteria

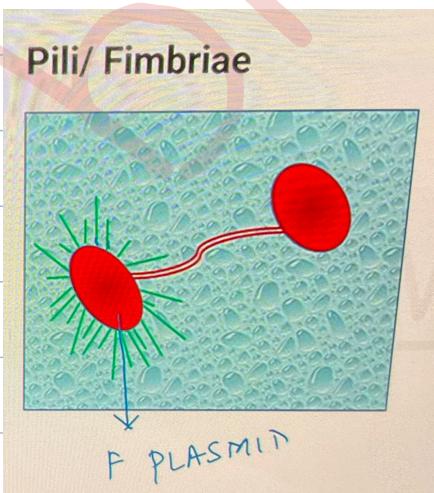

→  $1-1.5 \mu\text{m}$  long

→  $0.01 \mu\text{m}$  broad

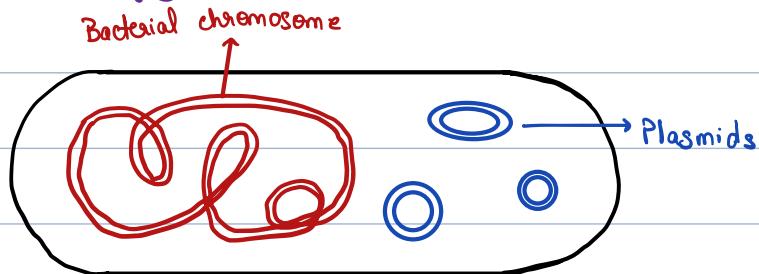

- Type IV pili in bacteria give them flagella-independent twitching motility
  - *Neisseria*
  - *Pseudomonas* .

### ② Sex Pili / Fimbriae : mediate conjugation

→ formed by both gram +ve & gram -ve bacteria , provided, they have the F-plasmid genes ['tra' genes].

Plasmids: extrachromosomal circular ds DNA molecules

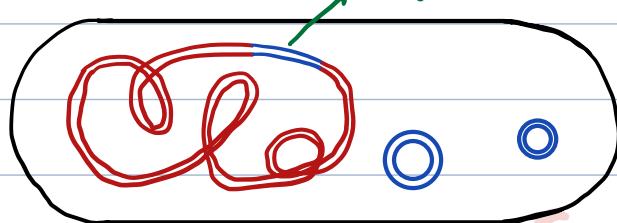

→ 1 - 40 plasmids / cell

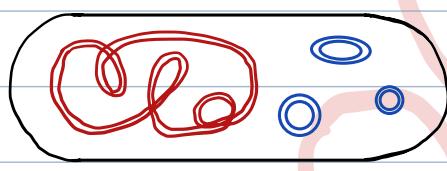

→ Plasmids are not essential  
for the life of the bacterium

→ Plasmids replicate independent of the chromosomes.

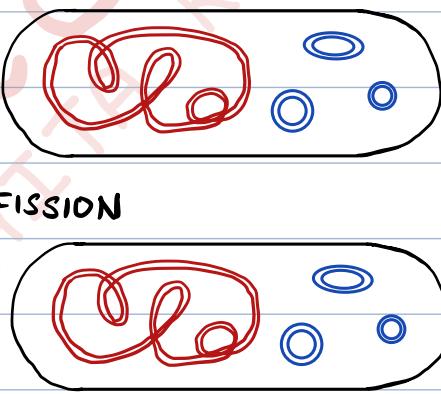

Plasmid-Epilome: plasmid integrated with chromosome  
integrated plasmid

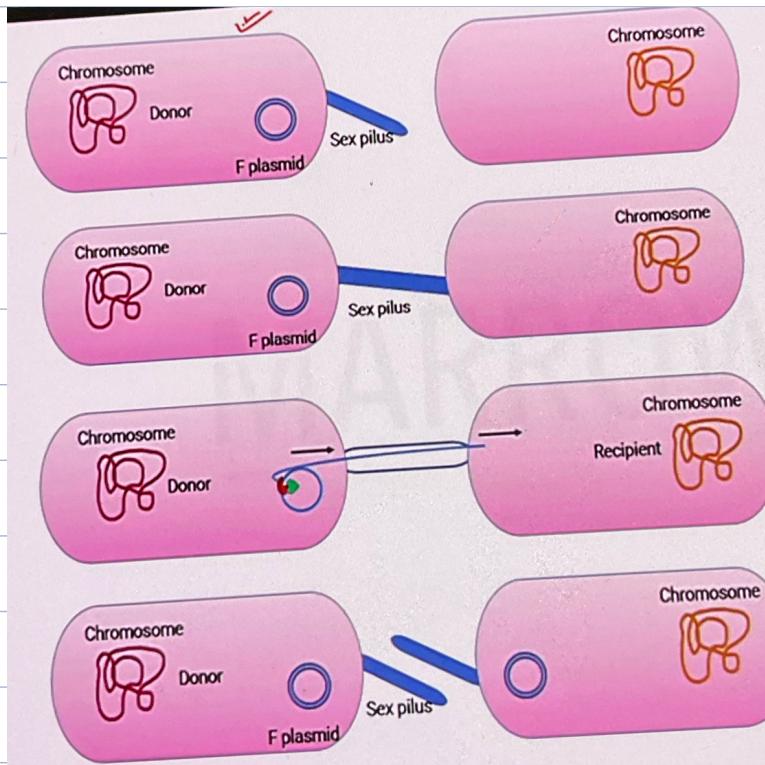

Plasmid Transfer: transferred vertically  
all plasmids

BINARY FISSION

Some plasmids are transferred horizontally: through sex pilus

→ those bacteria that have 'tra' gene (which encode sex pili) can transfer plasmids horizontally.

provide survival advantage to certain bacteria

**Bacteriocin:** Ab like small proteins which kill related bacteria.

{ • COLICIN      • KLEBOCINS  
• PYOCINS }

Plasmid Types: according to mode of transferred

Conjugative: → transferred vertically & horizontally

- F plasmid (fertility)
- R plasmid (fertility + <sup>Ab</sup> resistance genes)
- Col plasmid (fertility + bacteriocin coding genes)

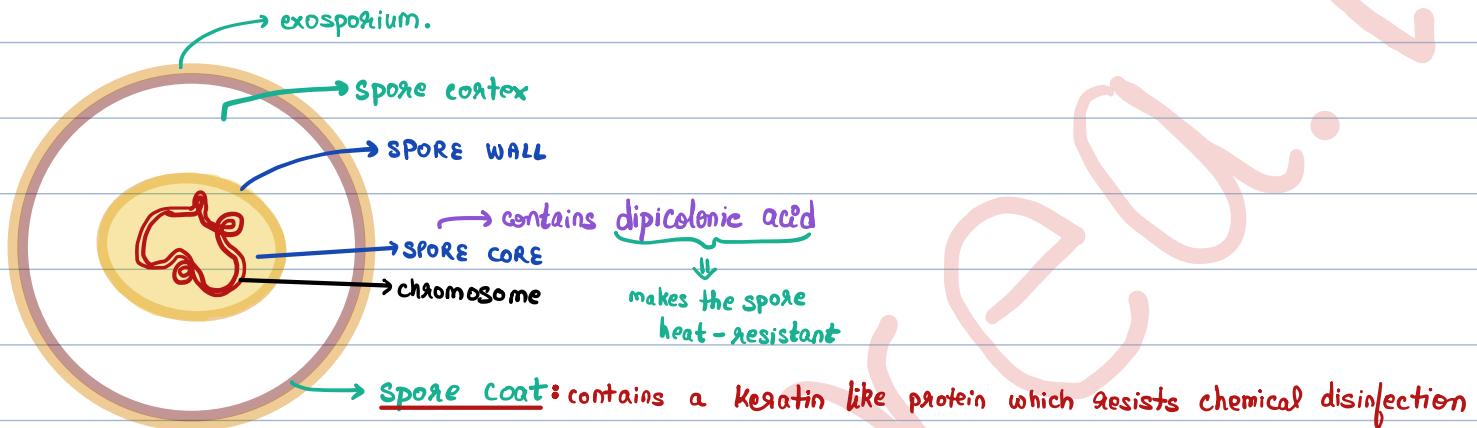

Non-conjugative: transferred vertically only

Plasmid Types: according to the genes present.

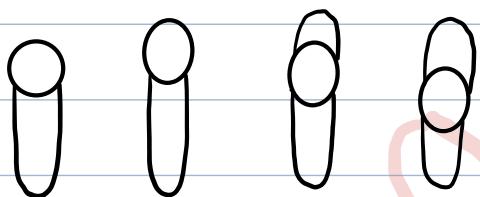

- Virulence: encode special virulence factors like endotoxin secretion, capsule, etc.
- Resistance: " Ab resistance genes.
- Fertility: " formation of sex pili.
- Metabolic: " enzymes to metabolize special substrates.
- Col plasmids: " bacteriocin production.

## Spore / Endospore : (helps in tiding over adverse conditions)

→ bacteria have the ability to form spores under environmental stress.  
(eg: extreme heat / nutrient depletion / dryness)

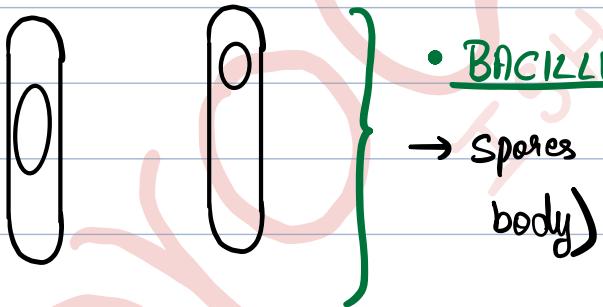

### 2 pathogenic genera which form spores:

#### Bulging spores of • CLOSTRIDIUM

- Spores form in soil, culture & human body

Except: *Clostridium perfringens*  
[causes gas gangrene]

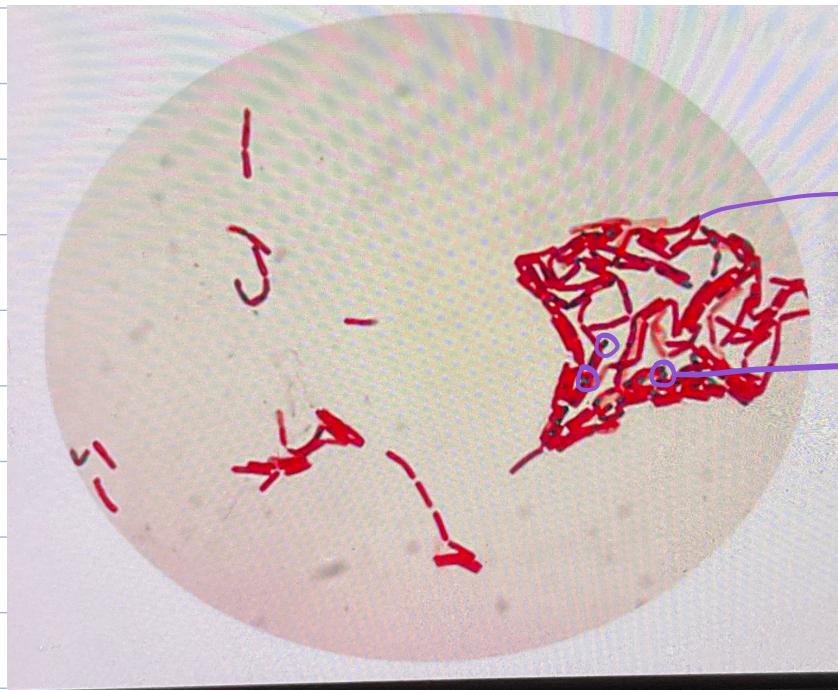

#### • BACILLUS (Non-bulging)

→ Spores form only in soil & culture (not in human body)

Demonstration of Spores: Spores do not take up grams' stain.

↳ stained by • Ashby Stain  
• Schaeffer Fulton Stain

bacteria stained by saffanine

spores stained by malachite green.

# Bacterial Physiology:

## Oxygen Requirements:

### STRICT AEROBES

→ Need oxygen to grow

Nagging Pests **Must**

**BB**reathe **For** **Life**

- Nocardia
- Pseudomonas aeruginosa
- Micrococcus
- Mycobacterium tuberculosis
- Brucella
- Bordatella
- Francisella
- Legionella

### STRICT ANAEROBES

→ cannot survive in the presence of oxygen ::

they lack enzymes  
Catalase, peroxidase  
& Superoxide dismutase

**Losers Choke By Air**

- Lactobacillus
- Clostridium
- Bacteroides
- Actinomyces
- Porphyromonas
- Prevotella
- Bifidobacterium
- Eubacterium

### FACULTATIVE ANAEROBES

→ aerobic organisms that are capable of switching to anaerobes in the absence of oxygen.

- Staphylococcus
- Streptococcus
- Enterobacteriaceae
- Corynebacterium
- Hemophilus

Aerotolerant: anaerobes but can grow in presence of small amounts of  $O_2$

Microaerophilic: require oxygen, but in small amounts (2-8% oxygen)

- Campylobacter
- Helicobacter
- Mycobacterium bovis
- Cultivable spirochetes

## pH Requirements:

### ACIDOPHILES

- grow  $< 6$
- *Lactobacillus*

### MESOPHILES / NEUTROPHILES

- grow between 6-8 pH
- [optimum pH: 7.2 - 7.4]
- most pathogenic bacteria

### ALKALIPHILES

- grow b/w 8-10 pH
- *Vibrio*
- *Alkaligenes*

## Temperature Requirements:

### Thermophiles

- best grow b/w 55 - 80°C
- *Thermus aquaticus*
- Taq polymerase for PCR

### Mesophiles

- most pathogenic bacteria
- grow best between 20 - 40°C
- [optimum temp: 35-37°C]

### Psychrophiles

- Best grow  $< 20^{\circ}\text{C}$ .

### Psychrotrophs

- best grow b/w 20 - 40°C
- but they can grow  $< 20^{\circ}\text{C}$ .
- *Listeria*
- *Yersinia*

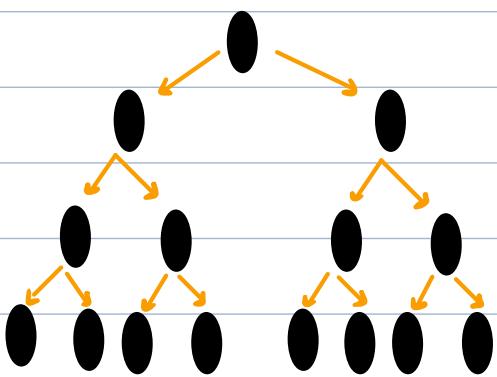

} method of cold enrichment is used to isolate them.

## Bacterial Growth Curve: Plotting no. of viable cells/mL periodically

→ bacteria divide by binary fission.

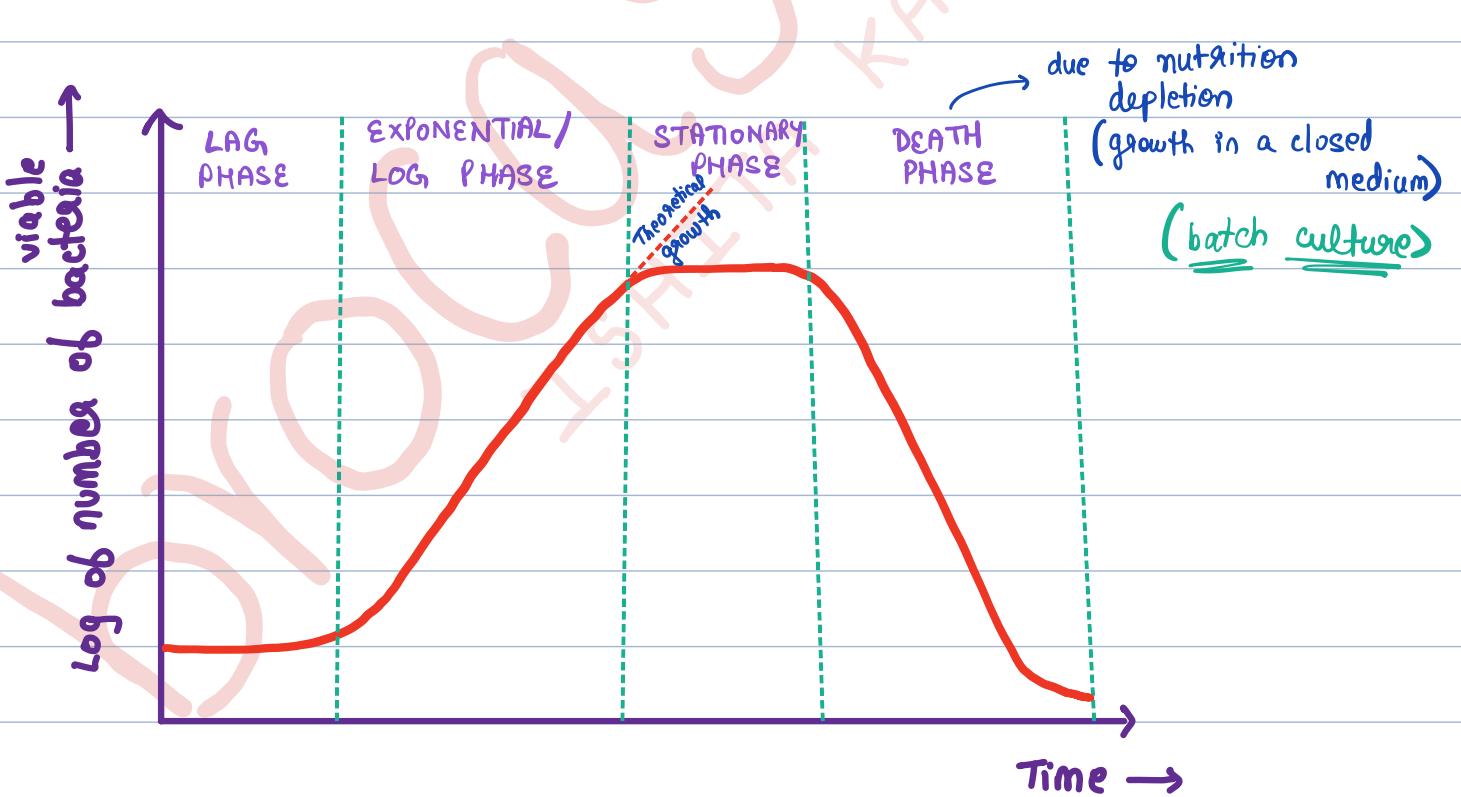

→ After  $n$  cycles of binary fission starting from a single bacterium,  
no. of bacteria produced =  $2^n$ .

Generation Time (Population Doubling Time): Time required for one binary fission

GT of:

- $\Sigma. \text{coli} = 20 \text{ min}$
- $M. \text{tb} = 20 \text{ hrs}$
- $M. \text{leprae} = 20 \text{ days}$

Lag Phase: stage of adaptation

- bacteria are metabolically active
- no replication occurs
- viable count & total count are constant.
- size of bacterium is maximum just at the end of lag phase
- variable for different bacterium.

Exponential / Log Phase: stage of active binary fission

- stage of exponential increase in number of bacteria ( $2^n$ )
- increasing viable count & total count
- size of bacterium  $\Rightarrow$  small
- stains uniformly
- adding Ab's is going to have maximal effect.
- Metabolically most active phase.

Stationary Phase: gradual nutrient depletion & collection of toxic metabolites

- No. of bacteria multiplying = No. of bacteria dying
- viable count: constant
- Total count: increasing
- Sporulation occurs
- Ab & exotoxins are secreted by bacteria.

Death / Declining Phase: total nutrient depletion

- no further replication
- bacteria are dying
- Viable count: falls

→ involution forms

Total count: constant

## Batch culture:

- a closed system where all the medium components are placed at the start of cultivation
- Microorganisms go through 4 phases
  - Lag phase
  - Log phase
  - Stationary phase
  - Death phase

## Continuous Culture:

→ fresh nutrients are added & toxic metabolites are removed at regular intervals.

Quorum Sensing: a process that allows the bacteria to coordinate their gene expression according to the density of the population.

→ first demonstrated in Vibrio fischeri (light emitting)
